## **Completions of ordered magmas**

BRUNO COURCELLE University of Bordeaux-I

JEAN-CLAUDE RAOULT IRIA, Parisq XI Received March 29, 1978 AMS Categories : 06A75, 18A40, 68A05

**Abstract.**We give a completion theorem for ordered magmas (i.e. ordered algebras with monotone operations) in a general form. Particular instances of this theorem are already known, and new results follow. The semantics of programming languages is the motivation of such investigations.

Key words complete partial orders, semantics of programming languages.

**Introduction.** When defining recursive functions by systems of equations (Kleene [5]), one introduces an order relation which means that a partial result approximates another one. This partial order is *complete* (i.e. every ascending chain admits a least upper bound), thus allowing a minimal solution to be defined for the system.

This matter has been rebuilt by Scott, and many authors after him, within the framework of *complete lattices*; that last theory has been developed for its own sake by several authors, among which Birkhoff [1].

Frequently, the lattice structure does not seem necessary and creates instead additional troubles (Plotkin [9], Milner [8] for instance). The notion of complete partial order is good enough, and fits better to the most common instances.

This algebraic framework is suitable for studying program schemes([2], [3]). We then need distinguish between the *base functions* and the *program-defined functions*, with the help of base functions and various control structures (recursive call, iteration, etc...).

Thus, our domains will be *ordered magmas*, i.e. partial orders equipped with *monotone* operators (no information is lost during a computation). And we shall be concerned with *completeness* (the operators being supposed *continuous*).

More precisely, we shall study the possible embeddings of an ordered magma into a complete ordered magma. Some of the ascending chains may keep their l.u.b., or may be added a new one; this gives different *completions*, each characterized by a universal property. We shall thus define the  $\Gamma$ -*completion* as the completion which preserves the l.u.b. which already exist in a set  $\Gamma$  of subsetes of the magma. From this general theorem is defived the "ideal completion" of [9], [1], [2], [4], the "chain-completion" of [8], and the existence of factor objects in the category of ordered magmas. The above mentionned authors woule use neither operators not magmas, but only partial orders (except [4]). But eht "chain-completion" in the category of partial orders need not be a complete ordered magma (cf. Corollary 2).

**Definitions and the main theorem.** Let F be a set of operators with arity. An F-magma M is a domain  $D_M$  together with a function  $f_M : D_M^k \to D_M$  for each  $f \in F$  with arity k. The homomorphisms of F-magmas, or F-morphisms, shall be compatible with the operators :  $\varphi : M \to M'$  is a F-morphism when

$$\varphi(f_{\mathbf{M}}(a_1,\ldots,a_k)) = f_{\mathbf{M}'}(\varphi(a_1),\ldots,\varphi(a_k))$$

for all  $f \in F$  with arity k, and all  $a_1, \ldots, a_k \in D_M$ .

In this paper, we shall only consider *ordered* magmas (therefore "magma" will mean "ordered magma"), with a partial order denoted by  $\leq_M$ , a least element  $\Omega_M$  (associated with the symbol  $\Omega$  of arity 0 which is always supposed to be an element of F), and monotone operators  $f_M$ . An F-morphism between ordered magmas must be monotone.

Finally, if M is a magma, a *sub*-F-*magma* N of M is a F-magma such that  $D_N \subseteq D_M$ , and that the inclusion  $i: n \to M$  is a (monotone) F-morphism. It is *full* when  $d \leq_M d'$  implies  $d \leq_N d'$  for every  $d, d' \in D_N$ .

Let  $\Gamma$  denote a set of non-empty subsets of  $D_M$ . The F-magma M is said to be  $\Gamma$ -complete when

- every A ∈ Γ admits a l.u.b. in D<sub>M</sub>, denoted by sup A or  $\bigvee_{x \in A} x$ ;
- $-f_m(A_1, \dots, A_k) = \{f(a_1, \dots, a_k); a_1 \in A_1, \dots, a_k \in A_k\} \in \Gamma \text{ and } \sup f_M(A_1, \dots, A_k) = f_M(\sup A_1, \dots, \sup A_k) \text{ for all } f \text{ with arity } k \text{ and all } A_1, \dots, A_k \in \Gamma.$

A monotone function  $\varphi : M^k \to N$  where M is  $\Gamma$ -complete and N is an arbitrary magma is  $\Gamma$ -continuous if for all  $A_1, \ldots, A_k \in \Gamma$ ,  $\varphi(A_1, \ldots, A_k)$  admits a l.u.b. in N and

$$\sup_{N} \varphi(A_1, \dots, A_k) = \varphi(\sup_{M} A_1, \dots, \sup_{M} A_k).$$

With each F-magma M is naturally associated

 $\Xi(M)$  = the set of non-empty subsets of  $D_M$ ,

 $\Phi(M)$  = the set of non-empty finite subsets of  $D_M$ ,

 $\Delta(M)$  = the set of non-empty directed subsets of  $D_M$ 

 $(A \in \Delta(M) \iff \forall d, d' \in A, \exists d'' \in A \ d \le d'' \text{ and } d' \le d'',$ 

 $\Delta_{\alpha}(M)$  = the set of non-empty directed subsets of cardinality at most  $\alpha$ ,

 $\Lambda(M)$  = the set of non-empty directed subsets of  $D_M$  which admit a l.u.b. in  $D_M$ ,

 $\Theta_{\alpha}(M)$  = the set of monotone morphisms of an ordinal  $\alpha$  into M (the  $\alpha$ -chains), etc.

Hence  $-\Lambda \subseteq \Delta \subseteq \Xi$ .

Thus, a partial order is a complete lattice (cf. Birkhoff [1]) if and only if it is  $\Xi$ -complete, a join-semi-lattice if and only if it is  $\Phi$ -complete, a lattice if and only if it is  $\Phi$ -complete with

$$\Phi'(\mathbf{M}) = \{ \{ d' \in \mathbf{D}_{\mathbf{M}}; d' \le d_1 \& \dots \& d' \le d_k \}; k \in \mathbf{N}, d_1, \dots, d_k \in \mathbf{D}_{\mathbf{M}} \}.$$

A F-magma is *pre-complete* if and only if it is  $\Lambda$ -complete. Notice that this condition only affects the  $f_m$ 's. If F only contains symbols of arity 0, then every F-magma is precomplete (cf. corollaries 1 and 2, and theorem 3).

To each of these families  $\Gamma$  is attached a category the objects of which are the  $\Gamma$ -complete F-magmas, and the arrows of which are the monotone F-morphisms  $f : \mathbf{M} \to \mathbf{N}$  that send a subset  $\mathbf{A} \in \Gamma(\mathbf{M})$  on a subset  $f(\mathbf{A})$ in  $\Gamma(\mathbf{N})$  and furthermore such that  $f(\sup \mathbf{A}) = \sup f(\mathbf{A})$ : the  $\Gamma$ -continuous morphisms. These restrictions can be automatically satisfied by the monotone morphisms for some families, but it is not always the case, as noticed for  $\Lambda$ . In the sequel, we shall restrict ourselves to those "functorial" families and related morphisms.

The main theorem of this paper reads as follows.

THÉORÈME 1. — Let  $\Gamma \subseteq \Gamma'$  two families of subsets, and M a  $\Gamma$ -complete F-magma. There exists a  $\Gamma'$ -complete F-magma  $M_{\Gamma}^{\Gamma'}$  and a  $\Gamma$ -continuous injective F-morphism  $i : M \to M_{\gamma}^{\Gamma'}$  such that for all  $\Gamma$ -continuous morphisms  $j : M \to N$  where n is  $\Gamma'$ -complete, there exists a unique  $\Gamma'$ -continuous morphism  $h : M_{\Gamma}^{\Gamma'} \to N$  such that j = hi.

$$\begin{array}{ccc} \mathbf{M} & \xrightarrow{\iota} & \mathbf{M}_{\Gamma}^{\Gamma} \\ & j \searrow & \downarrow h \\ & \mathbf{N} \end{array}$$

*Proof*: The construction of  $M_{\Gamma}^{\Gamma'}$  will be carried out in the particular case when  $\Gamma' = \Xi$ .

A non-empty subset A of D is  $\Gamma$ -closed when

(1)  $d \leq d'$  and  $d' \in A \Rightarrow d \in A$  (hence  $\Omega_M \in A$ ),

(2)  $B \subseteq A$  and  $B \in \Gamma \Rightarrow \sup B \in A$ .

The intersection of a family of closed subsets is closed; therefore

— for all non-empty subset A of D, there exists a smallest closed subset containing A, its *closure*, denoted by  $C_{\Gamma}(A)$  or C(A) when Γ is clear from the context;

— the set  $\hat{D}$  of non-empty sebsets of D ordered by set inclusion is a complete lattice : for all family  $(A_i)_{i \in I}$  (which contains  $\Omega_D$ )

$$\bigwedge_{i \in I} \mathbf{A}_i = \bigcap_{i \in I} \mathbf{A}_i$$
$$\bigvee_{i \in I} \mathbf{A}_i = \mathbf{C} \big(\bigcup_{i \in I} \mathbf{A}_i\big)$$

The lattice  $\hat{D}$  is given a structure of an F-magma by setting for all closed subsets  $C_i \in \hat{D}$ 

$$f_{\hat{D}}(C_1, \ldots, C_k) = C(\{f_M(d_1, \ldots, d_k; d_i \in C_i\}).$$

One checks that, for all subsets  $A_1, \ldots, A_k$  of D

(\*) 
$$C(f_M(C(A_1),\ldots,C(A_k))) = C(f_M(A_1,\ldots,A_k)).$$

As a result,  $\hat{D}$  is a complete F-magma; let us check it for the first argument :

$$f_{\hat{D}}(\bigvee_{i} A_{i}, B_{2}, \dots, B_{k}) = f_{\hat{D}}(C(\bigcup_{i} A_{i}), B_{2}, \dots, B_{k})$$
$$= C(f_{M}(\bigcup_{i} A_{i}, B_{2}, \dots, B_{k})) \quad \text{from } (*)$$
$$= C(\bigcup_{i} f_{M}(A_{i}, B_{2}, \dots, B_{k}))$$
$$= \bigvee_{i} f_{\hat{D}}(A_{i}, B_{2}, \dots, B_{k})$$

because for all family of subsets  $P_i$ ,  $C(\cup P_i) = C(\cup C(P_i))$  holds since C is a closure operation (Birkhoff [1], p. 111). The corresponding F-magma is denoted by  $M_{\Gamma}^{\Xi}$ .

DEFINITION OF *i*. Let  $i : D \to \hat{D}$  be defined by  $i(d) = C(\{d\}) = \{x \in D; x \le d\}$ . Clearly  $d \le d' \iff i(d) \le i(d')$ ; furthermore, *i* is  $\Gamma$ -continuous : if  $d = \sup A$  with  $A \in \Gamma$ , one shoud have

$$i(d) = \{x \in \mathbf{D}; x \le d\} = \bigvee_{x \in \mathbf{A}} i(x).$$

Now that last element is C(A) and since  $A \in \Gamma$ , sup  $A = d \in C(A)$ .

Finally, (\*) shows that *i* is an F-morphism.

CONSTRUCTION OF  $M_{\Gamma}^{\Gamma'}$ . Set  $E_0 = \{i(d); d \in D\}$  and let E denote the smallest subset of  $\hat{D}$  containing  $E_0$  which is  $\Gamma'$ -complete (i.e. such that  $\bigvee_i A_i \in E$  for all family  $(A_i)_{i \in I}$  in  $\Gamma'(E)$ ). It can be described more explicitly by

$$\begin{split} & E = \bigcup_{\alpha} E_{\alpha} & (\alpha \text{ is an ordinal}), \\ & E_{\alpha+1} = E_{\alpha} \cup \{\sup_{\hat{D}} X; \; X \in \Gamma'(E_{\alpha})\}, \\ & E_{\beta} = \bigcup_{\alpha < \beta} E_{\alpha} & \text{ if } \beta \text{ is a limit ordinal.} \end{split}$$

In fact,  $E = E_{\gamma}$  for some ordinal  $\gamma$  because  $\hat{D}$  is a set. Notice that

$$E_1 \supseteq \{C(A); A \in \Gamma'(D)\}$$

Since the subsets of  $\Gamma'$  are sent by f onto subsets of  $\Gamma'$ , E is invariant under  $f_{\hat{D}}$ . Hence  $(E, \subseteq, (f_E)_{f \in F})$  is a sub-F-magma of  $M_{\Gamma}^{\Xi}$  ( $f_E$  is the restriction of  $f_{\hat{D}}$  to E) which is  $\Gamma'$ -complete for the induced order. We shall denote it by  $M_{\Gamma}^{\Gamma'}$ .

UNIVERSAL PROPERTY OF  $(i, \mathbf{M}_{\Gamma}^{\Gamma'})$ . Let  $j : \mathbf{M} \to \mathbf{N}$  be a  $\Gamma$ -continuous morphism into a  $\Gamma'$ -complete F-magma. We shal define  $h : \mathbf{M}_{\Gamma}^{\Gamma'} \to \mathbf{N}$  by transfinite induction : h is defined over  $i(\mathbf{D}) = \mathbf{E}_0$  by the condition  $hi = j : h(\mathbf{C}(\{d\}) = j(d))$ .

Suppose that *h* is defined over  $E_{\alpha}$  for all  $\alpha < \beta$ . Then, if  $\beta$  is a limit ordinal, then *h* is defined over  $E_{\beta} = \bigcup_{\alpha < \beta} E_{\alpha}$ . Else *h* is defined by the  $\Gamma'$ -continuity : if  $e \in E_{\beta} - E_{\alpha}$  then

$$e = \sup X$$
 where  $X \in \Gamma'(E_{\alpha})$ 

and  $\{h(x); x \in X\} \in \Gamma'(N)$  admits a l.u.b. *n* in N. We set

h(e) = n,

so that *h* is now defined over  $E_{\beta}$ . By induction, it is defined over E, and is clearly  $\Gamma'$ -continuous by construction. Finally, one can check that *h* is indeed a morphism, i.e. that it is compatible with the operators.

This construction generalizes the completion of Markowski-Rosen [7] and Markowski [6] with the introduction of operators (cf. theorem 3 and corollary 4) and that of Bleicher-Schneider [2] by using a parameterized notion of limits and continuity. That last possibility is also considered in [10].

Since the magma  $M_{\Gamma}^{\Gamma'}$  is completely specified, it is the object function of a functor from the category of  $\Gamma$ -complete magmas to that of  $\Gamma'$ -complete magmas, and is a left adjoint to the obvious "forgetful" functor. From this fact, it can be deduced easily that if  $\Gamma \subseteq \Gamma' \subseteq \Gamma''$ , then

$$(\mathbf{M}_{\Gamma}^{\Gamma'})_{\Gamma'}^{\Gamma''} = \mathbf{M}_{\Gamma}^{\Gamma''}.$$

**II. Consequences of theorem 1.** An important point in the proof of the theorem is that all morphisms should belong to the appropriate category, including the functions  $f_M$ . It goes without saying when  $\Gamma$  is  $\Xi$  of  $\Phi$  or even  $\Delta$ , that any monotone function will send a subset of  $\Gamma(M)$  onto another subset of  $\Gamma(M)$  (or  $\Gamma(N)$  if it is a morphism  $M \to N$ ). It is not so obvious when  $\Gamma$  is  $\Lambda$ : this was the purpose of the remark following the definition of a precomplete magma.

If M is a lattice, i.e. a  $\Phi'$ -complete ordered set,  $M_{\Phi'}^{\Xi}$  is exactly the ideal completion as defined by Birkhoff ([1] theorem 5 p. 113).

If M is also a F-magma, the corresponding object in the category of all  $\Delta$ -complete F-magmas is  $M_{\emptyset}^{\Delta}$ . One checks easily that its domain is the set of non-empty ideals. In particular, if M = M(F) is the *free ordered* F-*magma* (identified with the set of finite terms over alphabet F), the corresponding object is the *free*  $\Delta$ -complete F-magma (from theorem 1), which can also be identified with the set of *infinite terms* or *trees*, as defined in [3], [4] (and [6] with a somewhat different terminology).

*Completion by cuts.* Let M be a *precomplete* F-*magma*, i.e. a A-complete, magma where A is the set of directed subsets of M which admit a l.u.b. In this case,  $M_{\Lambda}^{\Delta}$  is a completion of M which preserves the already existing l.u.b.'s of directed sets, and corresponds to the completion by cuts in lattices as defined by Birkhoff ([1], theorem 22, p. 126). This construction can also be found in Markowski [6]. These results are regrouped in the following corollary.

COROLLAIRE 2. — Let M be an oredered (resp. precomplete) F-magma. There exists a  $\Delta$ -complete F-magma  $M^{\Delta}_{\emptyset}$  (resp.  $M^{\Delta}_{\Lambda}$ ) such that M is a full sub-magma (and furthermore the inclusion  $i : M \to M^{\Delta}_{\Lambda}$  is  $\Lambda$ -continuous), and for all  $\Delta$ -complete F-magma N, and all morphisms  $j : M : \to N$  (resp.  $\Lambda$ -continuous morphisms), there exists a unique  $\Delta$ -continuous morphism  $k : M^{\Delta}_{\emptyset} \to N$  (resp.  $k : M^{\Delta}_{\Lambda} \to N$ ) extending j.

*Remark* : It is necessary for M to be precomplete if it is to be embedded in a complete ordered magma  $M_{\Lambda}^{\Delta}$ , so that

COROLLAIRE 3. — A magma is precomplete if and only if it is a full  $\Delta$ -sub-magma of a  $\Delta$ -complete magma.

Notice that if M is not precomplete,  $M_{\Lambda}^{\Delta}$  is an F-magma with domain  $\Delta$ -complete but the  $f_{\overline{M}}$  are not  $\Delta$ -continous. This point will be dealt with in corollary 4. We shall use  $\overline{M}$  as an other notation for  $M_{\Lambda}^{\Delta}$ .

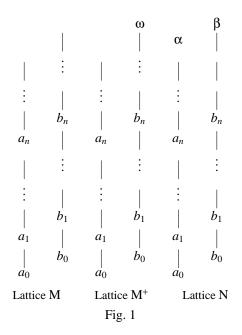

*Remarks* : McNeille's construction given in Birkhoff [1] consists in taking the set of all subsets of the lattice to be completed, then their upper bounds, and finally the sets of lower bounds of these upper bounds, as elements of the completed domain. But it does not give the desired result when applied to a precomplete magma.

Anyway, McNeille's completion does not satisfy the expected universal property.

An example is shown on figure 1.

Let  $M^+$  denote McNeille's completion of lattice M. The inclusion  $i : M \to N$  is a lattice-morphism which preserves all l.u.b.'s (and all g.l.b.'s) existing in M. It does not extend into a morphism of complete lattices  $M^+ \to N$ .

**III.** Quotients of complete F-magmas. Let M be a  $\Gamma$ -complete F-magma, for some  $\Gamma \in \Delta$ , and  $\pi$  an F-preorder over M, i.e. a preorder over D<sub>M</sub> such that

1)  $d \le d'$  entails  $d \pi d'$  for all  $d, d' \in D_M$ ,

2)  $d_i \pi d'_i$  for i = 1, ..., k entails  $f_M(d_1, ..., d_k) \pi f_m(d'_1, ..., d'_k)$ , and furthermore, which is  $\Gamma$ -continuous, i.e. 3) for all  $A \in \Gamma$  and all  $d' \in D_M$  such that  $d \pi d'$  for all  $d \in A$ , then (sup A)  $\pi d'$ .

Let  $M/\pi$  be the ordered F-magma quotient of M by the equivalence associated with the preorder  $\pi$  (i.e.  $d \pi d'$ and  $d' \pi d$ ),  $h_{\pi}$ :  $M \to M/\pi$  the natural epimorphism,  $\Gamma$ -continuous from 3) and  $\Gamma(M/\pi) = \{h_{\pi}(A); A \in \Gamma\}$ . Then we have the following theorem.

THEOREM 2. — Let M be a  $\Gamma$ -complete F-magma for  $\Gamma \subset \Gamma'$  and  $\pi$  a  $\Gamma$ -continuous preorder on M. Then there exists a  $\Gamma$ -continuous morphism with kernel  $\pi$ 

$$i: \mathbf{M} \to (\mathbf{M}/\pi)^{\Gamma}_{\Gamma}$$

in a  $\Gamma'$ -complete magma, such that for all  $\Gamma$ -continuous morphism  $j : \mathbb{M} \to \mathbb{N}$  whose kernel contains  $\pi$ , there exists a unique  $\Gamma'$ -continuous morphism  $k : (\mathbb{M}/\pi)_{\Gamma}^{\Gamma'} \to \mathbb{N}$  such that j = ki.

The *kernel* of a morphism  $i: M \to M'$  is the preorder  $\kappa$  such that  $d \kappa d'$  iff  $i(d) \leq_{M'} i(d')$ .

*Proof*: Clearly the magma<sup>M</sup>/ $\pi$  is  $\Gamma(M/\pi)$ -complete and  $h_{\pi}$ :  $M \to M/\pi$  is  $\Gamma$ -continuous. We apply theorem 1 and get  $(M/\pi)_{\Gamma}^{\Gamma'}$  which is  $\Gamma'$ -complete and a  $\Gamma$ -continuous morphism i':  $M/\pi \to (M/\pi)_{\Gamma}^{\Gamma'}$  the kernel of which is the order on  $M/\pi$ . The morphism  $i = i'h_{\pi}$ :  $M \to (M/\pi)_{\Gamma}^{\Gamma'}$  is thus  $\Gamma$ -continuous with kernel  $\pi$ .

All morphisms  $j: M \to N$  with kernel containing  $\pi$  can be factored into the composition

$$M \xrightarrow{h_{\pi}} M/\pi \xrightarrow{f} N_{f}$$

and j' is  $\Gamma(M/\sharp pi)$ -continuous. From theorem 1, there exists a unique  $\Gamma'$ -continuous  $k : (M/\pi)_{\Gamma}^{\Gamma'} \to N$  such that j' = ki', hence  $j = j'h_{\pi} = ki'h_{\pi} = ki$ .

This proof can be illustrated by the following commutative diagram which determines completely j' and k:

$$\begin{array}{cccc} \mathbf{M} & \stackrel{h_{\pi}}{\longrightarrow} & \mathbf{M}/\pi & \stackrel{i'}{\longrightarrow} & (\mathbf{M}/\pi)^{\Gamma}_{\Gamma} \\ & j \searrow & \downarrow j' & \swarrow k \\ & \mathbf{N} \end{array}$$

COROLLARY 3. — Let M be a  $\Delta$ -complete F-magma. The  $\Delta$ -continuous F-preorders on M are exactly the kernels of  $\Delta$ -continuous morphisms into  $\Delta$ -complete F-magmas.

One derives also the following generalization of corollary 1 for magmas which are not precomplete.

THEOREM 3. — Let M be an ordered F-magma. There exists a  $\Delta$ -complete F-magma  $\overline{M}$  and a  $\Delta$ -continuous morphism  $i : M \to \overline{\overline{M}}$  such that for all  $\Delta$ -complete F-magma N and  $\Delta$ -continuous morphism  $j : M \to N$ , there exists a unique  $\Delta$ -continuous morphism  $k : \overline{\overline{M}} \to N$  such that j = ki.

*Proof* : Let  $(D, \leq)$  be a preorder. An element *d* of D is a l.u.b. of A  $\subseteq$  D when

1)  $d \leq d'$  for all  $d' \in A$ ,

2) *d* is smaller than all upper bounds of A, i.e.  $d' \le d''$  for all  $d' \in A$  implies that  $d \le d''$ .

Notice that A may well have several l.u.b.'s. Let M be an ordered F-magma.

There exists a least F-preorder  $\pi \subset M \times M$  such that

(\*\*) if A<sub>1</sub>,... A<sub>k</sub> are  $\pi$ -directed subsets of D<sub>M</sub> with l.u.b.'s  $\delta_1$ ,...,  $\delta_k$  respectively, and if the  $\pi$ -directed subset  $f_M(A_1, ..., A_k)$  admits an upper bound  $\delta$  for  $\pi$ , then  $f_M(\delta_1, ..., \delta_k) \pi \delta$ .

We claim that  $M/\pi$  is precomplete and satisfies the following universal property : for all  $\Delta$ -continuous F-morphism j :  $M \rightarrow N$  in a  $\Delta$ -continuous F-magma N, there exists a unique  $\Delta$ -continuous F-morphism  $k : M/\pi \rightarrow N$  such that  $j = kh_{\pi}$  ( $h_{\pi}$  being the natural epimorphism  $M \rightarrow M/\pi$ ). The theorem will be deduced from corollary 1 with  $\overline{\overline{M}} = \overline{M/\pi}$ .

Let  $A \subseteq D_M$ ,  $A' = h_{\pi}(A) \in D_{M/\pi}$ , and  $h_{\pi}(d)$  the l.u.b. of A'. It is easy to see that A is directed for  $\pi$  and D is one of the l.u.b.'s of A for  $\pi$ . If  $A_1', \ldots, A_k' \in \Delta_{M/\pi}$  admit l.u.b.'s  $h_{\pi}(d_1), \ldots, h_{\pi}(d_k)$  and  $d = f_M(d_1, \ldots, d_k)$ , we must show that  $h_{\pi}(d)$  is the l.u.b. of  $f_{M/\pi}(A_1', \ldots, A_k')$ . Now, since  $\pi$  is an F-preorder,

$$f_{M/\pi}(h_{\pi}(a_1),\ldots,h_{\pi}(a_k)) = h\pi(f_m(a_1,\ldots,a_k)) \le h_{\pi}(f_M(d_1,\ldots,d_k)) = h_{\pi}(d).$$

On the other hand, if  $h_{\pi}(d') \ge f_{M/\pi}(A_1', \dots, A_k')$ , then d' is an upper bound of  $f_M(A_1, \dots, A_k)$  with respect to  $\pi$ ; hence  $f_M(d_1, \dots, d_k) \ \pi d'$ , i.e.  $h_{\pi}(d) \le h_{\pi}(d')$ , QED.

Therefore the following diagram in which  $\overline{M}$  exists even if M is not precomplete is commutative :

COROLLARYN 4. — The morphism h is onto. It is one-to-one if and only if for all  $A_1, \ldots, A_k \in \Delta_M$  such that  $f(A_1, \ldots, A_k) \in \Delta_M$  then

$$f(\sup A_1, \ldots, \sup A_k) = \sup f_M(A_1, \ldots, A_k)$$

*Proof*: On one hand, if the condition holds, then  $\leq_M$  itself satisfies (\*\*), hence  $\pi = \leq_M$ .

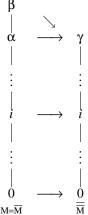

Therefore  $\overline{M} = \overline{M/\pi} = \overline{M}$ .

On the other hand, suppose that *h* is one-to-one, and that  $A_1, \ldots, A_k$ ,  $f_M(A_1, \ldots, A_k) \in \Delta_M$  with respective l.u.b.'s  $\delta_1, \ldots, \delta_k, \delta$ , and  $\delta' = f_M(\delta_1, \ldots, \delta_k)$ . Obviously  $\delta \leq \delta'$ . But  $\delta' \pi \delta$  entails that  $i_2(\delta) = i_2(\delta')$ . Since *h* is one-to-one, and the diagram commutes,  $i_1(\delta) = i_1(\delta')$ . Since  $i_1$  is th inclusion  $M \subset \overline{M}$ , the same holds in  $M : \delta = \delta'$ , QED.

EXAMPLE. Let M denote the F-magma  $N \cup \{\alpha, \beta\}$  ordered by  $i \leq_M j \leq_M \alpha \leq_M \beta$  for  $i \leq j$  in N. The only element of N is of arity one defined by

$$\begin{cases} f(i) = i & \text{if } i \in \mathbb{N}, \\ f(\alpha) = f(\beta) = \beta, \end{cases}$$

which is not  $\Delta$ -continuous. Since the domain of M is  $\Delta$ -complete, as an ordered set,  $\overline{M} = M$ . But in order to have a continuous f, one must identify  $\alpha$  and  $\beta$ , thus obtaining  $\overline{\overline{M}}$  with domain  $N \cup \gamma$  and  $h : \overline{M} \to \overline{\overline{M}}$ , as shown by figure 2.
