Abstract

A strong edge-colouring of a graph $G$ is a proper edge-colouring such that every path of three edges uses three colours. An induced matching of a graph $G$ is a subset $I$ of edges of $G$ such that the graph induced by the endpoints of $I$ is a matching. In this paper, we prove the NP-completeness of strong 4, 5 and 6-edge-colouring and maximum induced matching in the case of some restricted subclasses of subcubic planar graphs. We also obtain a tight upper bound for the minimum number of colours in a strong edge-colouring of outerplanar graphs as a function of the maximum degree.

Key words: Strong edge-colouring, induced matching, NP-completeness, planar graphs, outerplanar graphs.

1. Introduction

A proper edge-colouring of a graph $G = (V, E)$ is an assignment of colours to the edges of the graph such that no two adjacent edges use the same colour. A strong edge-colouring (called also distance 2 edge-colouring) of a graph $G$ is a proper edge-colouring of $G$, such that every path of length 3 $(uvxy)$ uses three different colours. We will say that two edges $uv$ and $xy$ are at distance 2 if these edges are not adjacent and there exists an induced path $uvxy$ of length 3. We denote by $\chi'_s(G)$ the strong chromatic index of $G$ which is the smallest integer $k$ such that $G$ can be strong edge-coloured with $k$ colours. The girth of a graph is the length of its shortest cycle. We use $\Delta$ to denote the maximum degree of a graph. We will say that two edges $uv$ and $xy$ are at distance 2 if $u, v, x, y$ are all distinct and the graph induced by $\{u, v, x, y\}$ contains at least three edges.

Strong edge-colouring seems to be introduced by Fouquet and Jolivet in [5, 6]. For a brief survey of applications of this type of colouring and some open questions, we refer the reader to [13]. In 1985, during a seminar in Prague, Erdős and Nešetřil gave a construction of graphs having strong chromatic index equal to $4\Delta^2$ when $\Delta$ is even and $\frac{1}{2}(5\Delta^2 - 2\Delta + 1)$ when $\Delta$ is odd. They conjectured that the strong chromatic index is bounded by this values and it was verified for $\Delta \leq 3$. Faudree \textit{et al.} [3] conjectured that every bipartite graph has a strong edge-colouring with $\Delta^2$ colours. In [4] the same authors stated a new conjecture, claiming that the strong chromatic index of planar subcubic graphs is at most 9 and proved that $\chi'_s(G) \leq 4\Delta + 4$, for planar graphs with $\Delta \geq 3$. In this paper we improve the latter result in the case of outerplanar graphs, showing that for an outerplanar graph $G$, $\chi'_s(G) \leq 3\Delta - 3$, for $\Delta \geq 3$. The interest in this bound is motivated by the existence of a class of outerplanar graphs having $\chi'_s(G) = 3\Delta - 3$, for any $\Delta \geq 3$.

Mahdian proved in [10] that $\forall k \geq 4$ deciding whether a bipartite graph with girth $g$ is strongly edge $k$-colourable, is NP-complete. He also proved that the problem can be solved in polynomial time for chordal graphs. In [12] Salavatipour gave a polynomial time algorithm for strong edge-colouring of graphs of bounded tree-width. In this paper we prove the NP-completeness of the problems of deciding whether a planar subcubic bipartite graph can be strong edge-coloured with four, five and six colours, for some values of the girth.

A related notion to strong edge-colouring is the induced matching. An induced matching of $G$ is a set of non-adjacent edges (matching) such that no two of them are joined by an edge in $G$. Clearly, the strong edge-colouring is a partition of the set of edges into a collection of induced...
matchings (see [3, 4]). Cameron proved [1] that finding a maximum induced matching in chordal graphs can be done in polynomial time and that the problem is NP-complete for bipartite graphs for every girth $g$. Lozin proved in [9] that recognizing whether a graph $G$ has an induced matching of size at least $k$, is an NP-complete problem even when $G$ is bipartite and of maximum degree 3. Duckworth et al. proved in [2] that the problem is NP-complete even when restricted to planar cubic graphs. We strengthen these results by proving that the problem remains NP-complete even if it is restricted to bipartite planar graphs with maximum degree 3 with girth $g$ for any fixed $g$.

2. Strong edge-colouring

2.1. NP-completeness for subcubic planar graphs

The STRONG EDGE $k$-COLOURING problem is defined as follows:

INSTANCE: A graph $G$.

QUESTION: Does $G$ have a strong edge-colouring with $k$ colours?

The 3-COLOURING problem is defined as follows:

INSTANCE: A graph $G$.

QUESTION: Does $G$ have a proper colouring with three colours?

3-COLOURING is proved to be NP-complete even when restricted to planar graphs with maximum degree 4 [7]. We will reduce this restricted version of 3-COLOURING in order to prove the theorems of this section.

**Theorem 1.** STRONG 4-EDGE-COLOURING is NP-complete for planar graphs with maximum degree 3 and any fixed girth and also for planar bipartite graphs with maximum degree 3 and any fixed even girth.

**Proof**

The problem is in NP since it can be checked in polynomial time whether a given edge-colouring is a strong edge-colouring. We reduce 3-COLOURING of planar graphs with maximum degree 4.

First, observe that by using the graphs in Figures 1a and 1b, we can force the edges at arbitrarily large distance to have the same colour if we put a sufficient number of claws between them (the dotted part of the figures). Moreover, depending on the parity of the number of claws between the edges having the same colour in a strong 4-edge-colouring, we can force vertices incident to these edges to be in the same part or in distinct parts of the bipartition. As an illustration in the Figures 1a and 1b, the bipartition is given by small and big vertices.

Given a planar graph $G$ with maximum degree 4, we construct a graph $G'$ as follows. Every vertex $u$ in $G$ is replaced by a copy $Q_u$ of the graph $Q$ depicted in Figure 3a which contains three copies of the graph $M$ shown in Figure 2. Note that $M$ is bipartite (the bipartition is given in the picture by the big and small vertices) and of arbitrarily large girth. Therefore $Q$ is bipartite and of arbitrarily large girth.

For every edge $uv$ in $G$, if $uv$ is the $i$th (respectively $j$th) edge incident to $u$ (respectively $v$) in the same cyclic ordering, then we connect $x_i$ of $Q_u$ with $x_j$ of $Q_v$ and one of the vertices $y^1_i$, $y^2_i$ with one of the vertices $y^1_j$, $y^2_j$ such that the obtained graph is planar. These connections are done using an arbitrarily large number of claws as depicted in Figure 3b. The obtained graph $G'$ is of maximum degree 3 and by the choice of the number of claws connecting the vertices, it is also bipartite and with an arbitrarily large girth. Finally, this graph can be built in polynomial time.

Up to a permutation of colours, the strong 4-edge-colouring of $M$ given in Figure 2 is unique.

We say that the colour of $Q$ is the colour of the edges incident to the vertices $x_i$ in $Q$ (colour 2 in...
Figure 2: Sub-gadget $M$

Figure 3: (a) Vertex gadget $Q$

Figure 3: (b) Connecting two vertex gadgets in $G'$

Also, the **forbidden colour of $Q$** is the colour of the edges incident to $y^1_i$ and $y^2_i$ (colour 3 in Figure 3a).

Figure 3b shows that for every edge $uv \in G$, $Q_u$ and $Q_v$ have distinct colours and the same forbidden colour. Since $G$ is connected, all copies of $Q$ have same forbidden colour, say 3, and thus no copy of $Q$ is coloured 3.

If $G$ is 3-colourable, then for every vertex $v \in G$, we can assign the colour of $v$ to $Q_v$ and extend this to a strong 4-edge-colouring of $G'$. Conversely, given a strong 4-edge-colouring of $G'$, we obtain a 3-COLOURING of $G$ by assigning the colour of $Q_v$ to the vertex $v$. So $G'$ is strong 4-edge-colourable if and only if $G$ is 3-colourable, which completes the proof.

**Theorem 2.** STRONG 5-EDGE-COLOURING is NP-complete for planar bipartite graphs with maximum degree 3 and girth 8, and for planar graphs with maximum degree 3 and girth 9.

**Proof**

In the following we will give the proof for the case of girth 8 since the same argument applies for the case of girth 9.

Similarly to the proof of Theorem 1, the problem is clearly in NP.
Given a planar graph $G$ with maximum degree 4 of an instance of 3-COLOURING of planar graphs of maximum degree 4, we construct a graph $G'$ as follows. Every vertex $v$ in $G$ is replaced by a copy $Q_v$ of the vertex gadget $Q$ depicted in Figure 4. For every edge $uv$ in $G$, we identify a vertex $x_i$ of $Q_u$ with a vertex $x_j$ of $Q_v$ and add a vertex of degree 3 adjacent to the common vertex of $Q_u$ and $Q_v$, as depicted in Figure 6. We identify these vertices in such a way that the obtained graph $G'$ is planar. Small and big vertices in Figure 4 show that $Q$ is bipartite and thus $G'$ is bipartite too. Moreover, $G'$ has no cycle of size strictly less than 8, hence $G'$ has girth 8.

Figure 4: Vertex gadget for the case of girth 8 of Theorem 2

We claim that up to permutation of colours, the strong 5-edge-colouring of $Q$ given in Figure 4 is unique. To see this, first observe that the strong 5-edge-precolouring of the subgraph of $Q$ depicted in Figure 5a, cannot be extended to the whole subgraph without using a sixth colour. Therefore, if it is possible to give a strong 5-edge-colouring of $Q$, the only way to do it is using the strong 5-edge-precolouring of this subgraph of $Q$ as depicted in Figure 5b. Now, using this observation, it is easy to prove that up to permutation of colours the strong 5-edge-colouring of $Q$ is unique and is the one given in Figure 4.

We say that the colour of $Q$ is the colour of the edges $x_iy_i$ in $Q$ (colour 1 in Figure 4. Also, the forbidden colours of $Q$ are the colours of the edges incident to $y_i$ in $Q$, different from $x_iy_i$ (colours 2 and 3 in Figure 4). Figure 6 shows that for every edge $uv \in G$, $Q_u$ and $Q_v$ have distinct colours.

Figure 5: Two possible 5-edge-precolourings of the graph of Figure 4

Figure 6: Edge gadget for the case of girth 8 of Theorem 2
and same forbidden colours. Since $G$ is connected, all copies of $Q$ have same forbidden colours, 2 and 3, and thus no copy of $Q$ is coloured 2 or 3.

If $G$ is 3-colourable, then for every vertex $v \in G$, we can assign the colour of $v$ to $Q_v$ and extend this to a strong 5-edge-colouring of $G'$. Conversely, given a strong 5-edge-colouring of $G'$, we obtain a 3-COLOURING of $G$ by assigning the colour of $Q_v$ to the vertex $v$. So $G'$ is strong 5-edge-colourable if and only if $G$ is 3-colourable, which completes the proof.

For the case of girth 9 the same argument applies by using as a vertex gadget the graph of Figure 7, while the edge gadget is the same. However, checking that the strong 5-edge-colouring of this gadget is unique (as given in the figure) is much more tedious than for the vertex gadget of girth 8. For the detailed proof we refer the reader to the Ph.D. thesis of one of the authors [13].

**Theorem 3.** STRONG 6-EDGE-COLOURING is NP-complete for planar bipartite graphs with maximum degree 3.

**Proof**

Again, same argument as in the proof of Theorem 1 shows that the problem is in NP.

For a graph $G$ of an instance of 3-COLOURING of planar graphs with maximum degree 4 we construct a graph $G'$ such that $G$ is 3-colourable if and only if $G'$ is strong 6-edge-colourable.

![Figure 7: Vertex gadget for the case of girth 9 of Theorem 2](image7)

We first want to point out two easy but very useful observations.

**Observation 1.** In any strong 6-edge-colouring of the graphs of Figure 8a, the colours of the edges at distance 3 have to be the same (colours 1 and 2 are forced).

**Observation 2.** For any strong 6-edge-colourable subcubic graph with an embedding such that two edges coloured distinctly cross each other in the plane, there exists a strong 6-edge-colourable subcubic planar graph obtained by replacing each crossing by five cycles of length 4 as depicted in Figure 8b.

![Figure 8: Transporting a colour in a strong 6-edge-colouring](image8)
Following Observation 1, in the graph $P$ of Figure 9, up to a permutation, in any strong 6-edge-colouring the colours 1 and 2 are forced. We call pendant edges the edges of $P$ incident to a vertex of degree one and coloured 1 and 2 in the figure. Note that $P$ is bipartite.

Next, we construct the vertex gadget as depicted in Figure 10a. Note that the colours $a, b, c, d$ in the figure are the colours which must be the same in any strong 6-edge-colouring. Take two copies of graph $P$ with six pairs of pendant edges (coloured \{a, b\} and \{c, d\} respectively) and connect them such that the colours $a, b, c, d$ are all distinct and the obtained graph has eight pairs of pendant edges. It is easy to see that the obtained graph $Q$ is planar, bipartite, subcubic, and such that $\chi'_s(Q) = 6$.

Now, we build the vertex gadget i.e., the graph $G_v$ that will replace a vertex $v$ of $G$ in $G'$. Take a copy of the graph $Q$ and choose an embedding such that there are four quadruples of edges coloured $a, b, c$ and $d$ in this order. Note that each crossing of edges is replaced by a cycle of length 4 following the Observation 2 such that the obtained graph is planar. Consider four pendant edges (one for each quadruple) of the obtained graph having the same colour, say colour $a$. For every of these edges, label its incident vertex of degree 1, $x_v^i$ ($1 \leq k \leq 4$).

For an edge $uv$ of $G$, in $G'$ we identify the vertices $x_u^i$ and $x_v^j$ and connect the other three pairs of edges as shown in Figure 10b. Note that if $G'$ is connected, in any strong 6-edge-colouring of $G'$ the colours 4, 5 and 6 used in Figure 10b are not used to colour any edge incident to some vertex labelled $x_v^i$. Observe that the construction of $G'$ can be done in polynomial time.

We claim that the obtained graph $G'$ is strongly 6-edge-colourable if and only if $G$ is 3-colourable. Similarly to the proof of Theorem 1, the forbidden colours in a strong 6-edge-colouring of the graph $G'$ are the colours of edges not incident to some vertex labelled $x_v^i$. Hence, in $G'$ there are three forbidden colours. If $G$ is 3-colourable then we can assign the colour of a vertex $v$ of $G$ to the pendant edge of $G_v$ incident to $x_v^i$ in $G'$ and extend this colouring to a valid strong 6-edge-colouring of $G'$. Conversely, given a strong 6-edge-colouring of $G'$, since there are three forbidden colours for $G'$, we can use the colour of the edge incident to $x_v^i$ in the graph $G_v$ to colour $v$ in $G$. 

□
2.2. Outerplanar graphs

**Theorem 4.** For every outerplanar graph $G$ with maximum degree $\Delta \geq 3$, $\chi'_s(G) \leq 3\Delta - 3$.

**Proof**
We define the partial order $\preceq$ on graphs such that $G_1 \prec G_2$ if and only if

- $|E(G_1)| < |E(G_2)|$ or
- $|E(G_1)| = |E(G_2)|$ and $G_1$ contains strictly more pendant edges than $G_2$.

Let $k \geq 3$ be an integer and $G$ be an outerplanar graph with maximum degree $k$ such that $\chi'_s(G) > 3k - 3$ and that is minimal with respect to $\preceq$.

We first show that $G$ does not contain Configuration 1 depicted in Figure 11a. That is, two adjacent vertices $x$ and $y$, such that the graph $G'$ obtained from $G$ by removing the set $S$ of edges incident to $x$ or $y$ contains two edges in distinct connected components.

Suppose that $G$ contains Configuration 1. Let $G_1, \ldots, G_k$ be the connected components of $G'$. Since they contain fewer edges than $G'$, by minimality of $G$ with respect to $\preceq$, the graphs induced by the edges of $G_i \cup S$ admit a strong edge-colouring with at most $3k - 3$ colours. Since the colours of the edges of $S$ are distinct, we can permute the colours in the colouring of $G_i \cup S$ so that the colouring of $S$ is the same in every $G_i \cup S$. By gluing up the graphs $G_i \cup S$, we obtain a valid strong edge-colouring of $G$ since the distance between an edge in $G_i$ and an edge in $G_{i'}$ for $i \neq i'$ is at least 3. This is a contradiction.

Configuration 2 depicted in Figure 11b consists of a vertex $v$ adjacent to at most one vertex $x$ with degree at least 2 and to at least one vertex $v$ of degree 1. This configuration cannot exist in $G$, as otherwise we could obtain a colouring of $G$ by extending a colouring of $G \setminus \{uv\}$.

![](image11.png)

Figure 11: Forbidden configurations

Let $G'$ be the graph induced by the vertices of $G$ of degree at least 2. Since Configuration 2 is forbidden in $G$, $G'$ has minimum degree 2.

We claim that $G'$ is 2-connected. Suppose the contrary and let $v$ be a vertex of $G'$ such that $G' - v$ is disconnected. Let $G'_1, \ldots, G'_l$ be the connected components of $G' - v$. Observe that each of the graphs $G'_i \cup N[v]$ with $i \in \{1, \ldots, l\}$ is smaller than $G$ with respect to $\preceq$ and thus for each of them there exists a strong edge-colouring $\phi_i$ using at most $3\Delta_i - 3$ colours, where $\Delta_i \leq k$ is the maximum degree of $G'_i \cup N[v]$. One can permute the colours of the edges incident to $v$ for every $\phi_i$ such that the colouring of the edges of $N[v]$ is the same in every $G'_i \cup N[v]$. The colourings $\phi_1, \ldots, \phi_k$ provide a valid strong edge-colouring of $G'$ and this is a contradiction.

Let $C$ be the cycle of the outer-face. Since Configuration 1 is forbidden in $G$, the chords of $C$ join vertices at distance 2 in the cyclic order. One can check that if $C$ contains at most 4 vertices then the theorem holds. So $C$ contains $n$ vertices $(n \geq 5)$ $v_1, \ldots, v_n$ in cyclic order and $G$ is the graph induced by the vertices of the cycle $C$ which can be adjacent to some vertices of degree 1.

Let us suppose that $C$ contains a chord, say the edge $v_2v_3$. Notice that since Configuration 1 is forbidden, $v_2$ is only adjacent to $v_1$ and $v_3$. The graph $G'$ is obtained from $G$ by splitting the vertex $v_2$ into $v'_2$, which is only adjacent to $v_1$, and $v''_2$, which is only adjacent to $v_3$. Notice that $G'$ and $G$ have the same number of edges but $G'$ has two more pendant edges than $G$, so $G' \prec G$. The graph $G'$ thus admits a valid strong edge-colouring using $3k - 3$ colours and this colouring remains valid if we identify $v'_2$ and $v''_2$ to form $G$ (no edges at distance at least 3 in $G'$ are at distance at most 2 in $G$). This shows that vertices of degree at least 2 in $G$ form a chordless cycle.
To finish the proof, we have to consider only the worst case of graphs of this form, where every vertex on the chordless cycle is incident to $\Delta(G) - 2$ pendant edges. It is easy to check that if $\Delta(G) = k = 3$, then we can colour $G$ using at most $3k - 3 = 6$ colours. We iteratively construct a suitable colouring for larger values of $k$: when $k$ is incremented by 1, there is at most one new pendant edge for each vertex on the cycle and three more available colours. We use the three new colours to colour the new edges such that two new edges incident to adjacent vertices get distinct colours. The graph of Figure 12 is the one for which at each step we need to add exactly three colours, thus reaching the bound of $3k - 3$ colours.

\[\square\]

3. Induced Matchings

The NP-complete problem PLANAR (3, $\leq$ 4)-SAT is defined as follows [8]:

**INSTANCE:** A collection $\mathcal{C}$ of clauses over a set $X$ of boolean variables, where each clause contains exactly three distinct literals (a variable $x_i$ or its negation $\overline{x_i}$) and each variable appears at most four times, such that the variable-clause incidence graph is planar.

**QUESTION:** Can $\mathcal{C}$ be satisfied, i.e., is there a truth assignment of the variables of $X$ such that each clause contains at least one true literal?

The INDUCED MATCHING problem is defined as follows:

**INSTANCE:** A graph $G$ and an integer $k$.

**QUESTION:** Is there an induced matching of size $k$ in $G$?

**Theorem 5.** INDUCED MATCHING is NP-complete for planar bipartite graphs with maximum degree 3 and any fixed girth.

**Proof**

The problem is clearly in NP: given a subset of edges of $G$, one can check in polynomial time whether it is an induced matching of $G$ by checking the distance in $G$ between each pair of edges of this subset.

We reduce PLANAR (3, $\leq$ 4)-SAT to INDUCED MATCHING. We first prove the result for planar graphs with maximum degree 3 and girth at most 12 and then explain how to restrict further the proof to bipartite graphs with any fixed girth.

For an instance of PLANAR (3, $\leq$ 4)-SAT with a collection of clauses $\mathcal{C}$ and a set $X$ of boolean variables, we build the graph $G$ as follows. For each variable, make a copy of the graph depicted in Figure 13a. For each clause $C_i$, make a copy of the graph $G_{C_i}$, by connecting each variable gadget as shown in Figure 13b such that $G$ is planar (this can be done since the variable-clause incidence graph is planar). The construction of $G$ can be done in polynomial time in terms of the size of $\mathcal{C}$.

We show that $\mathcal{C}$ is satisfiable if and only if $G$ contains an induced matching $I$ of size $k = 4|X| + |\mathcal{C}|$. 

![Variable gadget $G_x$](image1.png)

![Clause gadget $G_{C_i}$ for $C_i = \{\overline{x_1}, x_2, \overline{x_3}\}$](image2.png)

Figure 13: Variable and Clause gadgets
Suppose \( C \) is satisfiable. We build the induced matching \( \mathcal{I} \) of \( G \) as follows. For every variable subgraph \( G_x \), we put in \( \mathcal{I} \) the four edges belonging to the cycle that are not incident to a vertex corresponding to a literal with boolean value TRUE.

For every clause subgraph \( G_{C_i} \), we put in \( \mathcal{I} \) an edge incident to \( m_i \) and pointing in the direction of a literal with boolean value TRUE. Such a literal exists since the clause is satisfied. Clearly, \( \mathcal{I} \) is an induced matching and is of size \( k \).

Suppose now that \( G \) has an induced matching \( \mathcal{I} \) of size \( k \). We will show a truth assignment of the variables of \( X \) such that \( C \) is satisfiable.

For each variable gadget at most four of its edges belong to \( \mathcal{I} \). If exactly four edges of a variable gadget \( G_x \) belong to \( \mathcal{I} \), then no edge outside \( G_x \) and incident to one of the vertices of \( G_x \) can belong to \( \mathcal{I} \). Hence, for every subgraph \( G_{C_i} \), \( \mathcal{I} \) contains at least one of the edges incident to \( m_i \). Then, \( \mathcal{I} \) contains exactly one of the edges incident to \( m_i \) (say \( e_i \)). Let \( l_j \) be the edge of a vertex gadget adjacent to \( e_i \) and therefore corresponding to a literal \( l_j \). We build a set of edges \( \mathcal{I}' \) in the following way: for every clause gadget \( G_{C_i} \), \( e_i \in \mathcal{I}' \), and for every vertex gadget of \( G_{C_i} \), add to \( \mathcal{I}' \) all the edges adjacent to \( l_j \) and not adjacent to \( l_j \). Clearly, \( \mathcal{I}' \) is an induced matching and \( |\mathcal{I}'| = |\mathcal{I}| \). For every clause gadget \( G_{C_i} \), assign the value TRUE to the literal represented by the edge adjacent to \( e_i \). Hence every clause of \( C \) has a TRUE literal and therefore \( C \) is satisfiable.

In the proof above, the constructed graph is planar with maximum degree 3, but it is not bipartite and the girth is bounded (by 12). It is easy to see that it is possible to use cycles of size 6s for the variable gadgets and to branch the clause gadgets on them in such a way that the resulting graph is bipartite and has any given fixed girth. The reduction then uses \( k = 2s|X| + |C| \).
