## Abstract

We study deterministic broadcasting in radio networks in the recently introduced framework of network algorithms with *advice*. We concentrate on the problem of trade-offs between the number of bits of information (size of advice) available to nodes and the time in which broadcasting can be accomplished. In particular, we ask what is the minimum number of bits of information that must be available to nodes of the network, in order to broadcast very fast. For networks in which constant time broadcast is possible under complete knowledge of the network we give a tight answer to the above question:  $O(n)$  bits of advice are sufficient but  $o(n)$  bits are not, in order to achieve constant broadcasting time in all these networks. This is in sharp contrast with geometric radio networks of constant broadcasting time: we show that in these networks a constant number of bits suffices to broadcast in constant time. For arbitrary radio networks we present a broadcasting algorithm whose time is inverse-proportional to the size of advice.

*Key words:* radio network, distributed algorithm, deterministic broadcasting, advice

---

## 1. Introduction

### 1.1. The Framework and the Problem

We study deterministic broadcasting in radio networks in the recently introduced [18] framework of network algorithms with *advice*. This paradigm permits to investigate the minimum amount of information (size of advice) that nodes of the network have to be given in order to accomplish some distributed task with a given efficiency. In our present context the task is broadcasting in radio networks and the measure of efficiency is time.

A *radio network* is a collection of sites (stations) equipped with wireless transmission and receiving capabilities, with a distinguished node  $s$  called the source. The topology of a radio network is modeled as a directed graph  $G = (V, E)$ , where nodes in  $V$  represent sites of the network and oriented edges in  $E$  correspond to wireless connections. It is assumed that there is a directed path from the source to every other node. The existence of an edge  $(u, v)$  means that  $v$  is within the reach of  $u$ . We say that  $u$  is

an *in-neighbor* of  $v$  and  $v$  is an *out-neighbor* of  $u$ . Nodes that are not neighbors must communicate via intermediate (relaying) nodes. Similarly as in most papers in the literature on radio networks, we assume that communication is synchronous, i.e., all nodes have internal clocks that tick at the same rate, measuring consecutive time steps, referred to as *rounds*. All clocks show the same round number at any given time.

At any round every node can be either in the *transmitting* or in the *receiving* mode, i.e., a node cannot transmit and receive messages during the same round. When a node  $v$  transmits in round  $i$ , its message is delivered during this round to all out-neighbors of  $v$ . However, if  $w$  is an out-neighbor of  $v$ , this message is *heard* by  $w$ , i.e.,  $w$  receives the message correctly, if and only if the node  $v$  is the only in-neighbor of  $w$  that transmits during the round  $i$ . Otherwise a *collision* occurs at  $w$  and the message is not heard. An important property of radio networks is the *collision detection* capability, i.e., the ability of a node to differentiate collision from silence in a given round. All our results hold both with this assumption and without it. Indeed, our positive results (algorithms) are valid even without collision detection, and our impossibility results are valid even assuming this capability.

Among the large class of (arbitrary) radio networks, an important subclass consists of *geometric radio networks* (GRN). In the case of an approximately flat region without large obstacles, nodes that can be reached from  $u$  are those within a circle of radius  $r$  centered at  $u$ , and the positive real  $r$ , called the *range* of  $u$ , depends on the power of the transmitter located at  $u$ . Reachability graphs corresponding to such radio networks are called geometric radio networks. More precisely, they are defined as follows. We assume that there is a constant number  $\rho$  of possible powers of transmitters, thus we fix a set  $R = \{r_1, \dots, r_\rho\}$  of positive reals,  $r_1 < \dots < r_\rho$ , called *ranges*. Let  $C$  be a set of points in the plane with a distinguished source. Points of  $C$  are nodes of the graph (representing radio stations). Each point  $u \in C$  is assigned a range  $r(u) \in R$  and a directed edge  $(u, v)$  exists in the graph, if and only if the Euclidean distance between  $u$  and  $v$  does not exceed  $r(u)$ .

The number of nodes of a radio network is denoted by  $n$ , and the eccentricity of the source (the maximum length of all shortest paths in the graph from the source to all other nodes) is denoted by  $D$ . Throughout the paper,  $\log$  denotes the logarithm with base 2 and  $\ln$  denotes the natural logarithm. Nodes of a radio network have distinct labels from the set  $\{1, \dots, N\}$ , where  $N$  is polynomial in  $n$ . However, our negative results hold even when  $N = n$ . Moreover, nodes of a geometric radio network have also their  $(x, y)$  coordinates. A priori, each node of a (general) radio network knows only its own label, and each node of a GRN knows only its own label and its  $(x, y)$  coordinates, as well as the set  $R$  of available ranges (which has constant size). All other information about the network must be given to nodes as advice, to be defined below.

One of the most studied communication primitives in networks is *broadcasting*, also known as one-to-all communication. The source has a message that should be distributed to all other nodes in the network. The *time* of a deterministic broadcasting algorithm is the number of rounds in which all the nodes get the source message. With every radio network  $G$  we associate its optimal broadcasting time  $Opt(G)$ . This is the minimum time in which broadcasting in this network can be accomplished, if nodes have full information about the network. Establishing optimal broadcasting time for a given radio network is an NP-hard problem [5].

It remains to formalize the framework of advice (cf. [18]) in our present context. All additional knowledge available to the nodes of the network (in particular knowledge concerning the rest of the network), is modeled by an oracle providing advice. An *oracle* is a function  $\mathcal{O}$  whose arguments are labeled networks (in the case of geometric radio networks these arguments are actual sets of points in the plane, together with the assigned ranges and labels), and the value  $\mathcal{O}(G)$ , for a network  $G = (V, E)$ , called the *advice* provided by the oracle to this network, is in turn a function  $f : V \rightarrow \{0, 1\}^*$  assigning a binary string to every node  $v$  of the network. Intuitively, the oracle looks at the entire labeled network and assigns to every node some information, encoded as a string of bits. The *size* of the advice given by the oracle to a given network  $G$  is the sum of the lengths of all the strings it assigns to nodes. Hence this size is a measure of the amount of information about the network, available to its nodes. Solving the broadcasting problem in radio networks using advice provided by oracle  $\mathcal{O}$  consists in designing an algorithm that is *unaware* of the network  $G$  at hand but accomplishes broadcasting in it, as long as every node  $v$  of the network  $G$  is provided with the string of bits (advice)  $f(v)$ , where  $f = \mathcal{O}(G)$ .

The main interest of this framework is the significance of lower bounds on the size of advice. If we

have a broadcasting algorithm using some advice of size  $O(g(n))$  and achieving time  $O(T(n))$ , in  $n$ -node networks, and at the same time we prove that  $\Omega(g(n))$  is the lower bound on the size of advice needed to achieve time  $O(T(n))$ , this implies optimality in a very strong sense: smaller amount of information of *any* type cannot help to achieve broadcasting time  $O(T(n))$  using *any* algorithm. In other words, changing the type of information provided to nodes cannot help to achieve the same efficiency of broadcasting at lower information cost.

This paper is the first to consider communication in radio networks in the framework of algorithms with advice. Our research is motivated by the following problems:

- What is the minimum size of advice permitting to achieve broadcasting time  $O(\text{Opt}(G))$  for a radio network  $G$ ?
- What are the trade-offs between the size of advice and the time of broadcasting in radio networks?

### 1.2. Our Results

Our main focus is on radio networks with constant optimal broadcasting time, i.e., on networks in which deterministic broadcast in constant time is possible under complete knowledge of the network. For this class of networks we establish the minimum size of advice sufficient to achieve constant broadcasting time. We show that  $O(n)$  bits of advice are sufficient and  $o(n)$  bits are not sufficient, in order to achieve constant broadcasting time in all these networks. The main contribution of this part of the paper is the above tight lower bound on the size of advice. This is in sharp contrast with geometric radio networks of constant broadcasting time: we show that in these networks a *constant* number of bits of advice suffices to broadcast in constant time.

For arbitrary radio networks we show a trade-off between the size of advice and the time of deterministic broadcasting, by presenting a broadcasting algorithm whose time is inverse-proportional to the size of advice. More precisely, for any  $q \in O(n)$  we show an oracle which gives advice of size  $q$  to the nodes of a network, and an algorithm using this advice, which performs broadcasting in time  $O(\frac{nD}{q} \log^3 n)$  in any  $n$ -node network with source eccentricity  $D$ . As a corollary we get that for “short” networks, i.e., with  $D$  polylogarithmic in  $n$ , an advice of sublinear size suffices to achieve polylogarithmic broadcasting time.

### 1.3. Related Work

The paradigm of distributed computing with advice has been recently introduced in [18] and used there to study the task of broadcasting with a linear number of messages, in the message passing model. Subsequently, this approach has been used in [19] to study efficient exploration of networks by mobile agents, in [20] to study distributed graph coloring, in [21] to study the distributed minimum spanning tree construction, in [31] to study graph searching, and in [22] to study broadcasting in trees in the one-port model.

Broadcasting in radio networks is a topic extensively studied in the last twenty years. Most of the papers represented radio networks as arbitrary (undirected or directed) graphs. Models used in the literature about algorithmic aspects of radio communication, starting from the paper [5], differ mostly in the amount of information about the network that is assumed available to nodes. However, assumptions about this knowledge concern particular items of information, such as the knowledge of the size of the network, its diameter, maximum degree, or some neighborhood around the nodes, rather than limiting the total number of bits available to nodes, regardless of their meaning, as is the case with the advice approach.

Deterministic centralized broadcasting assuming complete knowledge of the network was considered, e.g., in [6], where a polynomial-time algorithm constructing a  $O(D \log^2 n)$ -time broadcasting scheme was given for all  $n$ -node networks of radius  $D$ . Subsequent improvements by many authors [16, 23, 24] were followed by the polynomial-time algorithm from [29] constructing a  $O(D + \log^2 n)$ -time broadcasting scheme, which is optimal. On the other hand, in [1] the authors proved the existence of a family of  $n$ -node networks of radius 2, for which any broadcast requires time  $\Omega(\log^2 n)$ .

One of the first papers to study deterministic distributed broadcasting in radio networks whose nodes have only limited knowledge of the topology, was [2]. The authors assumed that nodes know only their own label and labels of their neighbors. Many authors [4, 7, 8, 10, 11] studied deterministic distributed

broadcasting in radio networks under the assumption that nodes know only their own label (but not labels of their neighbors). In [7] the authors gave a broadcasting algorithm working in time  $O(n)$  for undirected  $n$ -node networks, assuming that nodes can transmit spontaneously, before getting the source message. For this model, a matching lower bound  $\Omega(n)$  on deterministic broadcasting time was proved in [27] even for the class of networks of constant diameter. Increasingly faster broadcasting algorithms working on arbitrary radio networks were constructed, the currently fastest being the  $O(n \log^2 D)$ -time algorithm from [12] and the  $O(n \log n \log \log n)$  algorithm from [13]. On the other hand, in [11] a lower bound  $\Omega(n \log D)$  on broadcasting time was proved for  $n$ -node networks of radius  $D$ .

Randomized broadcasting algorithms in radio networks were studied, e.g., in [2, 30]. For these algorithms, no topological knowledge of the network and no distinct identities of nodes were supposed. In [2] the authors showed a randomized broadcasting algorithm running in expected time  $O(D \log n + \log^2 n)$ . In [30] it was shown that for any randomized broadcasting algorithm and parameters  $D \leq n$ , there exists an  $n$ -node network of radius  $D$  requiring expected time  $\Omega(D \log(n/D))$  to execute this algorithm. It should be noted that the lower bound  $\Omega(\log^2 n)$  from [1], for some networks of radius 2, holds for randomized algorithms as well. A randomized algorithm working in expected time  $O(D \log(n/D) + \log^2 n)$ , and thus matching the above lower bounds, was presented in [12, 28].

Broadcasting in geometric radio networks and some of their variations was considered, e.g., in [14, 15, 32, 33]. In [33] the authors proved that scheduling optimal broadcasting is NP-hard even when restricted to such graphs, and gave an  $O(n \log n)$  algorithm to schedule an optimal broadcast when nodes are situated on a line. In [32] broadcasting was considered in networks with nodes randomly placed on a line. In [15] broadcasting with restricted knowledge was considered but the authors studied only the special case of nodes situated on the line. In [14], the authors investigated the impact of the size of the part of the geometric radio network known to nodes, on the efficiency of broadcasting. In particular they showed that with the full knowledge of the network broadcasting can be accomplished in (optimal) time  $O(D)$ , and if all nodes know only their own label, range and coordinates, broadcasting in time  $O(n)$  is possible. For symmetric geometric radio networks, time  $O(D + \log n)$  was proved optimal under this restricted knowledge, if collision detection is available. If it is not, the same broadcasting time was achieved if nodes know positions, labels and ranges of all nodes within a constant (arbitrarily small) positive radius. In a recent paper [17] the authors considered broadcasting in radio networks represented by unit disk graphs. They compared broadcasting time in two models: the model allowing spontaneous transmissions of nodes that have not yet gotten the source message, and the model in which only nodes that already obtained the source message can transmit.

## 2. Combinatorial Background

We will use Stirling estimates  $\sqrt{2\pi m}(m/e)^m \leq m! \leq 2\sqrt{2\pi m}(m/e)^m$ , for an integer  $m > 0$ ; in cases when we only assume that  $m \geq 0$  we will use only the estimate  $m! \geq (m/e)^m$ .

The following combinatorial lemmas will be used in further considerations.

**Lemma 1.** *If  $k^* \in o(k)$  then for any integer  $0 \leq \ell \leq k^*$  and for sufficiently large  $k$*

$$\binom{k}{k^* - \ell} \leq e^{-2\ell} \cdot \left(\frac{ke}{k^*}\right)^{k^*}.$$

PROOF. First note that

$$\begin{aligned} \binom{k}{k^*} &= \frac{k!}{(k^*)!(k-k^*)!} \leq \frac{k^k}{(k^*)^{k^*} \cdot (k-k^*)^{k-k^*}} \cdot \sqrt{\frac{2k}{k^* \cdot (k-k^*) \cdot \pi}} \\ &\leq \left(\frac{k}{k^*}\right)^{k^*} \cdot \left(\frac{k}{k-k^*}\right)^{k-k^*} \leq \left(\frac{ke}{k^*}\right)^{k^*}. \end{aligned}$$

For  $1 \leq \ell \leq k^*$  we have

$$\begin{aligned} \binom{k}{k^* - \ell} &= \frac{k^* - \ell + 1}{k - k^* + \ell} \cdot \binom{k}{k^* - \ell + 1} < \frac{k^*}{k - k^*} \cdot \binom{k}{k^* - \ell + 1} < \dots < \left(\frac{k^*}{k - k^*}\right)^\ell \cdot \binom{k}{k^*} \\ &\leq e^{-2\ell} \cdot \left(\frac{ke}{k^*}\right)^{k^*}, \end{aligned}$$

for sufficiently large  $k$ . □

**Lemma 2.** For fixed parameters  $z, b \geq 2$ , the real function

$$\prod_{1 \leq j \leq b} \left(\frac{1}{z(j)}\right)^{z(j)},$$

where  $0 \leq z(j) \leq z$  for any  $1 \leq j \leq b$  and  $z(1) + \dots + z(b) = z$ , achieves the maximum for  $z(j) = z/b$ .

PROOF. In order to prove the lemma, first note that we consider a continuous function on a compact set, therefore the function achieves its supremum in this set, thus the maximum exists. Suppose, to the contrary, that we could find two real numbers  $0 \leq z(j') < z(j^*) \leq z$  in the maximum solution. We show that after replacing each of them by  $(z(j') + z(j^*))/2$  we would get a larger value, which would be a contradiction, due to the fact that the modified  $b$ -tuple is also in the considered domain of the function. Indeed,

$$\begin{aligned} \prod_{1 \leq j \leq b} \left(\frac{1}{z(j)}\right)^{z(j)} &= \left(\frac{1}{z(j')}\right)^{z(j')} \cdot \left(\frac{1}{z(j^*)}\right)^{z(j^*)} \cdot \prod_{1 \leq j \leq b, j \neq j', j^*} \left(\frac{1}{z(j)}\right)^{z(j)} \\ &= \left(\frac{(z(j') + z(j^*))/2}{z(j')}\right)^{z(j')} \cdot \left(\frac{(z(j') + z(j^*))/2}{z(j^*)}\right)^{z(j^*)} \\ &\quad \cdot \left(\left(\frac{1}{(z(j') + z(j^*))/2}\right)^{(z(j') + z(j^*))/2}\right)^2 \cdot \prod_{1 \leq j \leq b, j \neq j', j^*} \left(\frac{1}{z(j)}\right)^{z(j)} \\ &< \left(\left(\frac{1}{(z(j') + z(j^*))/2}\right)^{(z(j') + z(j^*))/2}\right)^2 \cdot \prod_{1 \leq j \leq b, j \neq j', j^*} \left(\frac{1}{z(j)}\right)^{z(j)}. \end{aligned}$$

In order to justify the last inequality, we first prove that, for a fixed  $\xi > 0$ , the function  $f(s) = \frac{\xi^\xi}{s^s(\xi - s)^{\xi - s}}$ , with domain  $[0, \xi/2]$ , achieves the supremum (which is also a maximum due to the compact domain) for  $s = \xi/2$ . For  $s \in (0, \xi/2]$  we have

$$f'(s) = \frac{\xi^\xi}{s^s(\xi - s)^{\xi - s}} \cdot (-1 - \ln s + 1 + \ln(\xi - s)) = \frac{\xi^\xi}{s^s(\xi - s)^{\xi - s}} \cdot \ln \frac{\xi - s}{s},$$

which is equal to 0 only for  $s = \xi - s = \xi/2$ , and is strictly positive for  $0 < s < \xi/2$ . Also note that  $f(0) = 1 < 2^\xi$ . This means that  $f(s)$  achieves a strict maximum for  $s = \xi/2$  and consequently  $f(s) < f(\xi/2) = 2^\xi$ , for  $0 \leq s < \xi/2$ .

Setting  $\xi = z(j') + z(j^*)$  and  $s = z(j')$  we get

$$\begin{aligned} \left(\frac{(z(j') + z(j^*))/2}{z(j')}\right)^{z(j')} \cdot \left(\frac{(z(j') + z(j^*))/2}{z(j^*)}\right)^{z(j^*)} &= \frac{(z(j') + z(j^*))^{z(j') + z(j^*)}}{z(j')^{z(j')} \cdot z(j^*)^{z(j^*)}} \cdot 2^{-(z(j') + z(j^*))} \\ &< 2^{z(j') + z(j^*)} \cdot 2^{-(z(j') + z(j^*))} = 1, \end{aligned}$$

which concludes the proof of the lemma. □

The following lemma is the main combinatorial tool that we will use to establish our lower bound. More precisely, it will be used in the proof of Fact 1 in Section 3.

**Lemma 3.** *Let  $x, x_1, \dots, x_a$  be non-negative integers satisfying  $x \geq x_1 \geq \dots \geq x_a \geq 0$  and  $x_1 + \dots + x_a = 2x$ , where  $2 \leq a \leq x$ . The number of permutations of the set  $X = \{1, \dots, 2x\}$  satisfying the following condition:*

(\*) *for any  $1 \leq i \leq a$  and  $1 \leq j \leq x$ , no two elements from the interval  $X_i = [1 + \sum_{i'=1}^{i-1} x_{i'}, \sum_{i'=1}^i x_{i'}]$  are placed in positions  $2j - 1, 2j$*

is at most

$$\beta(2x, a) = \sqrt{2} \cdot (2x)! \cdot e^{2a^2 \ln(2ex/a) - x/a} .$$

PROOF. For given  $x, x_1, \dots, x_a$  satisfying the assumptions of the lemma, we call a permutation satisfying the condition (\*) an *allowed permutation*. The set  $\{2j - 1, 2j\}$  of positions will be called *group j*. We first prove the following claim.

**Claim.** For a given set  $X = \{1, \dots, 2x\}$  and number  $a$ , the largest number of allowed permutations occurs when  $x_1 = \dots = x_a = 2x/a$  (or the differences between them are at most 1, if  $2x/a$  is not an integer).

**Proof of the Claim:** In order to prove the claim, note that the maximum exists since the space is finite. Suppose, to the contrary, that the largest number of permutations occurs when there exist two intervals  $X_i, X_j$  satisfying  $0 \leq x_i \leq x_j - 2 \leq x - 2$ .

Let  $\gamma(2x - 2z)$ , for  $0 \leq z \leq x_i$ , stand for the number of allowed permutations of the set  $\{1, \dots, 2x - 2z\}$  partitioned into  $a - 1$  classes of sizes  $x_1, \dots, \hat{x}_j, \dots, \hat{x}_i, \dots, x_a, x_i + x_j - 2z$  respectively, where the notation  $\hat{x}_j, \hat{x}_i$  means that these two numbers are skipped from the list. Based on this, note that the number of allowed permutations in the original setting is given by the formula

$$\sum_{z=0}^{x_i} \left( \binom{x}{z} \binom{x_i}{z} \binom{x_j}{z} (z!)^2 \cdot 2^z \cdot \gamma(2x - 2z) \right) . \quad (1)$$

In the above formula, the sum corresponds to the different possible numbers  $z$  of blind groups containing only elements from  $X_i$  and  $X_j$  (that is, one element from  $X_i$  and one from  $X_j$ ). Fix such a number  $z$  between 0 and  $x_i$ . The first factor corresponds to the choice of the  $z$  groups among the  $x$  possible groups. The second, resp. third, factor corresponds to the choice of the  $z$  elements of  $X_i$ , resp. of  $X_j$ , that will belong to the  $z$  chosen groups. The fourth factor corresponds to the number of possible allocations of the previously chosen elements of  $X_i$  and  $X_j$  to the chosen groups. The fifth factor corresponds to the number of possible orderings of allocated elements inside the  $z$  groups. The final factor is the number of ways to complete the permutation so that no other element of  $X_i$  is paired with an element of  $X_j$  and so that the obtained permutation is an allowed one.

Consider this formula when classes  $X_i, X_j$  are replaced by classes  $X'_i, X'_j$ , where  $X'_i = X_i \cup \{y\}$  and  $X'_j = X_j \setminus \{y\}$  for  $y \in X_j$ . Note that by our assumption (which should lead to a contradiction), the number of allowed permutations in this second setting is not larger than in the original setting (since the original setting is assumed to have the largest number of allowed permutations among all settings with permutations of set  $X$  and a partition of  $X$  into  $a$  classes of size at most  $x$  each). On the other hand, observe that the number of allowed permutations in the second setting, obtained by replacing  $x_i$  by  $|X'_i| = x_i + 1$  and  $x_j$  by  $|X'_j| = x_j - 1$  in the formula (1), is

$$\sum_{z=0}^{x_i+1} \left( \binom{x}{z} \binom{x_i+1}{z} \binom{x_j-1}{z} (z!)^2 \cdot 2^z \cdot \gamma(2x - 2z) \right) . \quad (2)$$

Observe that the range of the sum in formula (2) is larger than in formula (1), and for every  $0 \leq z \leq x_i$  we have

$$\binom{x_i+1}{z} \binom{x_j-1}{z} = \binom{x_i}{z} \binom{x_j}{z} \cdot \frac{x_i+1}{x_i+1-z} \cdot \frac{x_j-z}{x_j} > \binom{x_i}{z} \binom{x_j}{z} ,$$

using inequality  $x_i + 1 < x_j$ . Therefore the number of allowed permutations in the second setting, expressed by the formula (2), is larger than in the original setting, expressed by the formula (1), which is a contradiction. This proves the Claim.  $\diamond$

In view of the Claim it is enough to show the upper bound on the number of allowed permutations under the assumption that  $x_i = 2x/a$  for every  $1 \leq i \leq a$ . To avoid rounding we assume that  $2x/a$  is an integer. (Otherwise the proof is similar but with rounding of numbers.) Note that  $x_i = 2x/a \geq 2$ , for every  $1 \leq i \leq a$ . Each allowed permutation defines a unique partition of each  $X_i$ , for  $1 \leq i \leq a$ , into sets

$$X_i(1), \dots, X_i(i-1), X_i(i+1), \dots, X_i(a), Y_i(1), \dots, Y_i(i-1), Y_i(i+1), \dots, Y_i(a),$$

where  $X_i(j), Y_i(j) \subseteq X_i$  correspond to the elements which are grouped with nodes in  $X_j$ , for  $j \neq i$  and such that  $1 \leq j \leq a$ , and additionally elements in  $X_i(j)$  are always placed on the odd positions while those in  $Y_i(j)$  are placed in even positions of the permutation. Let  $x_i(j) = |X_i(j)|$  and  $y_i(j) = |Y_i(j)|$ . It follows that  $0 \leq x_i(j) = y_j(i) \leq \min\{x_i, x_j\} = x_i = x_j$ . Note that  $\sum_{1 \leq i, j \leq a, i \neq j} x_i(j) = \sum_{1 \leq i, j \leq a, i \neq j} y_i(j) = x$ . Therefore, the number of allowed permutations is equal to the product of the following factors:

- (i) the number of all permutations of the groups, which is  $x!$ , and
- (ii) the sum, over all partitions of sets  $X_i$ , for  $1 \leq i \leq a$ , into subsets  $X_i(j), Y_i(j)$  for  $1 \leq j \leq a, j \neq i$ , such that  $|X_i| = |X_j|$  and  $|X_i(j)| = |Y_j(i)|$ , of the numbers of combinations of groups which could be created between sets  $X_i(j)$  and  $Y_j(i)$ , for all  $i \neq j$ , which is in fact  $\prod_{1 \leq i, j \leq a, j \neq i} (x_i(j))!$ .

It remains to estimate the number of summands in the formula for the number of allowed permutations in (ii). First note that for given integers  $x_i(j), y_i(j)$ , for  $1 \leq i, j \leq a$  and  $i \neq j$ , the number of different partitions of sets  $X_1, \dots, X_a$  into subsets  $X_i(j), Y_i(j)$ , for  $1 \leq j \leq a, j \neq i$ , is

$$\begin{aligned} & \prod_{1 \leq i \leq a} \prod_{1 \leq j \leq a, j \neq i} \binom{x_i - \sum_{j' < j} (x_i(j') + y_i(j'))}{x_i(j)} \cdot \binom{x_i - \sum_{j' < j} (x_i(j') + y_i(j')) - x_i(j)}{y_i(j)} \\ &= \prod_{1 \leq i \leq a} \frac{(x_i)!}{\prod_{1 \leq j \leq a, j \neq i} ((x_i(j))! \cdot (y_i(j))!)} \\ &= \frac{\prod_{1 \leq i \leq a} (x_i)!}{\prod_{1 \leq i, j \leq a, j \neq i} ((x_i(j))! \cdot (y_i(j))!)} \\ &= \frac{\prod_{1 \leq i \leq a} (x_i)!}{\prod_{1 \leq i, j \leq a, j \neq i} ((x_i(j))!)^2}. \end{aligned}$$

Therefore, for given sets  $X_i$ ,  $1 \leq i \leq a$ , and for given integers  $x_i(j), y_i(j)$ , for  $1 \leq i, j \leq a$  and  $i \neq j$ , satisfying the required conditions, the numbers of sets of groups which could be created in order to form an allowed permutation is

$$\frac{\prod_{1 \leq i \leq a} (x_i)!}{\prod_{1 \leq i, j \leq a, j \neq i} ((x_i(j))!)^2} \cdot \prod_{1 \leq i, j \leq a, j \neq i} (x_i(j))! = \frac{\prod_{1 \leq i \leq a} (x_i)!}{\prod_{1 \leq i, j \leq a, j \neq i} (x_i(j))!}.$$

Using Stirling estimates, the above formula can be estimated as follows:

$$\begin{aligned} \frac{\prod_{1 \leq i \leq a} (x_i)!}{\prod_{1 \leq i, j \leq a, j \neq i} (x_i(j))!} &\leq \frac{\prod_{1 \leq i \leq a} (x_i/e)^{x_i} \cdot \prod_{1 \leq i \leq a} 2\sqrt{2\pi x_i}}{\prod_{1 \leq i, j \leq a, j \neq i} (x_i(j)/e)^{x_i(j)}} \\ &\leq (2\sqrt{2\pi} \cdot 2x/a)^a \cdot e^{-2x+x} \cdot \left( \prod_{1 \leq i \leq a} (2x/a)^{2x/a} \right) \cdot \left( \prod_{1 \leq i, j \leq a, j \neq i} \frac{1}{(x_i(j))^{x_i(j)}} \right) \\ &\leq e^{2a \ln(2ex/a) - x} \cdot (2x/a)^{2x} \cdot \left( \prod_{1 \leq i, j \leq a, j \neq i} \frac{1}{(x_i(j))^{x_i(j)}} \right). \end{aligned}$$

In view of Lemma 2 and of the equation  $\sum_{1 \leq i, j \leq a, i \neq j} x_i(j) = x$ , the product

$$\prod_{1 \leq i, j \leq a, j \neq i} \left( \frac{1}{x_i(j)} \right)^{x_i(j)}$$

in the above formula is not larger than

$$\prod_{1 \leq i, j \leq a, j \neq i} \left( \frac{1}{x/[a(a-1)]} \right)^{x/[a(a-1)]} = \left( \frac{a(a-1)}{x} \right)^x.$$

Therefore we have

$$\begin{aligned} & \frac{\prod_{1 \leq i \leq a} (x_i)!}{\prod_{1 \leq i, j \leq a, j \neq i} ((x_i(j))!)^2} \cdot \prod_{1 \leq i, j \leq a, j \neq i} (x_i(j))! \\ & \leq e^{2a \ln(2ex/a) - x} \cdot (2x/a)^{2x} \cdot \left( \frac{a(a-1)}{x} \right)^x \\ & = e^{2a \ln(2ex/a) - x} \cdot (4x)^x \cdot \left( \frac{a-1}{a} \right)^x \\ & \leq e^{2a \ln(2ex/a) - x - x/a} \cdot (4x)^x. \end{aligned}$$

Second, we show how to bound the number of different sequences of integers  $x_i(j), y_i(j)$ , for  $1 \leq i, j \leq a$  and  $i \neq j$ , satisfying the required conditions:  $0 \leq x_i(j) = y_j(i) \leq x_i = x_j$  for  $1 \leq i, j \leq a$  and  $i \neq j$ , and  $\sum_{1 \leq j \leq a, j \neq i} (x_i(j) + y_i(j)) = x_i$  for any  $1 \leq i \leq a$ . It is at most

$$\begin{aligned} \prod_{1 \leq i \leq a} \binom{x_i + 2a - 3}{2a - 3} & \leq \prod_{1 \leq i \leq a} \left( \frac{(x_i + 2a - 3)^{x_i + 2a - 3}}{(2a - 3)^{2a - 3} x_i^{x_i}} \cdot \frac{2\sqrt{x_i + 2a - 3}}{\sqrt{2\pi(2a - 3)x_i}} \right) \\ & \leq \prod_{1 \leq i \leq a} \left( \left( \frac{x_i + 2a - 3}{2a - 3} \right)^{2a - 3} \cdot \left( \frac{x_i + 2a - 3}{x_i} \right)^{x_i} \right) \\ & \leq \prod_{1 \leq i \leq a} \left( \left( \frac{x}{2a - 3} + 1 \right)^{2a - 3} \cdot \left( \frac{x_i + 2a - 3}{x_i} \right)^{x_i} \right) \\ & \leq \prod_{1 \leq i \leq a} \left( e^{(2a - 3) \ln(x/(2a - 3) + 1)} \cdot e^{2a - 3} \right) \\ & \leq \prod_{1 \leq i \leq a} e^{(2a - 3) \ln(2ex/a)} \\ & \leq e^{2(a^2 - a) \ln(2ex/a)}, \end{aligned}$$

since  $2 \leq x_i, a \leq x$ , for any  $1 \leq i \leq a$ , and consequently  $x/(2a - 3) + 1 \leq 2x/a$ .

Putting the above estimates together, and using again Stirling estimates, the number of allowed permutations is at most

$$\begin{aligned} & \leq x! \cdot \prod_{1 \leq i \leq a} \binom{x_i + 2a - 3}{2a - 3} \cdot \frac{\prod_{1 \leq i \leq a} (x_i)!}{\prod_{1 \leq i, j \leq a, j \neq i} ((x_i(j))!)^2} \cdot \prod_{1 \leq i, j \leq a, j \neq i} (x_i(j))! \\ & \leq x! \cdot e^{2(a^2 - a) \ln(2ex/a)} \cdot e^{2a \ln(2ex/a) - x - x/a} \cdot (4x)^x \\ & \leq (x/e)^x \cdot 2\sqrt{2\pi x} \cdot e^{2a^2 \ln(2ex/a) - x - x/a} \cdot (4x)^x \\ & \leq (2x/e)^{2x} \cdot \sqrt{2} \cdot \sqrt{2\pi} \cdot 2x \cdot e^{2a^2 \ln(2ex/a) - x/a} \\ & \leq \sqrt{2} \cdot (2x)! \cdot e^{2a^2 \ln(2ex/a) - x/a}. \end{aligned}$$

This concludes the proof of Lemma 3. □

### 3. Broadcasting in Constant Time

In this section we focus on radio networks with constant optimal broadcasting time, i.e., on the class of networks in which broadcasting in constant time is possible if nodes have complete knowledge of the network. Such networks must of course have constant source eccentricity  $D$ . However, this is not a sufficient condition. Indeed, there are  $n$ -node networks with  $D = 2$ , whose minimum broadcasting time is  $\Omega(\log^2 n)$ , even if the network is completely known to all nodes (cf. [1]).

Networks with constant optimal broadcasting time may require a very long broadcasting time if their topology is unknown and in the absence of any advice. In [27] a family of such  $n$ -node networks was proved to require time  $\Omega(n)$ . In fact, even for the more restricted class of geometric radio networks, strong lower bounds of this type can be proven. Using techniques from [17] a class of geometric radio networks with constant optimal broadcasting time can be shown to require time  $\Omega(\sqrt{n})$ , if nodes know only their own label and coordinates. Therefore it is natural to ask how sensitive to advice is broadcasting time in networks (geometric or not) with constant optimal broadcasting time. More precisely, how much advice is needed to achieve constant broadcasting time in such networks.

First observe that for networks of the considered class,  $O(n)$  bits of advice are sufficient in order to achieve constant broadcasting time.

**Proposition 1.** *For any positive constant  $c$  let  $\mathcal{C}$  be the class of  $n$ -node radio networks whose optimal broadcasting time is at most  $c$ . There exists an oracle which gives advice of size  $O(n)$  to the nodes of networks of class  $\mathcal{C}$  and an algorithm using this advice, which performs broadcast in time at most  $c$ , for any network in class  $\mathcal{C}$ .*

PROOF. Fix a network  $C \in \mathcal{C}$  and consider an algorithm having complete knowledge of the network and broadcasting in time at most  $c$ . For any fixed node  $v$  of  $C$ , let  $t_1, \dots, t_k$  be numbers of rounds in which  $v$  has to transmit, according to this algorithm. The oracle gives this information, encoded as a string of bits of constant length, to node  $v$ . Hence the total size of advice is  $O(n)$ . Now the broadcasting algorithm simply makes node  $v$  transmit in rounds  $t_1, \dots, t_k$ .  $\square$

#### 3.1. Lower Bounds

The main result of this section shows that the above upper bound on the size of advice needed to achieve constant broadcasting time is tight, i.e., that  $o(n)$  bits of advice are not sufficient to broadcast in constant time.

**Theorem 1.** *For every integer function  $k^* \in o(n)$  there exist an integer function  $c^*$  such that  $c^*(n) \rightarrow \infty$  and a family of  $n$ -node networks with constant optimal broadcasting time, such that every algorithm using at most  $k^*(n)$  bits of advice requires time  $c^*(n)$  on some of them, for sufficiently large  $n$ .*

PROOF. Fix  $n$ . Consider the following family  $\mathcal{C}$  of  $n$ -node directed networks, see Fig. 1(a). Let  $k = \lfloor (n-1)/3 \rfloor$ . (We omit parameter  $n$  from the arguments of functions  $k, k^*, c^*$  since it is known from the context.) Each network in  $\mathcal{C}$  is composed of three layers. Layer  $L_0$  consists of the source with label 0. Layer  $L_1$  consists of  $2k$  nodes with labels from  $\{1, \dots, 2k\}$ , partitioned into  $k$  disjoint *groups* of size 2, and of  $n - (3k + 1)$  nodes with labels from  $\{3k + 1, \dots, n\}$ . Layer  $L_2$  consists of  $k$  nodes with labels from  $\{2k + 1, \dots, 3k\}$ . All nodes of layer  $L_1$  are out-neighbors of the source, and each node  $2k + i$  from layer  $L_2$  is the out-neighbor of both nodes from the  $i$ th group. There are no other edges in networks from  $\mathcal{C}$ . There are  $\delta = (2k)!/2^k$  different networks in this family. The optimal broadcasting time of any network from  $\mathcal{C}$  is clearly 2. Let  $c^* = \log \frac{k-k^*}{2^{k^*} \log(k\epsilon/k^*)}$ . Clearly,  $c^* \in \omega(1)$  for  $k^* \in o(k)$ . In view of  $k = \lfloor (n-1)/3 \rfloor$ , it is enough to prove that every algorithm using at most  $k^* \in o(k)$  bits of advice requires time larger than  $c^*$  on some network in  $\mathcal{C}$ . We fix  $n$  such that  $k$  is sufficiently large for the purpose of Lemma 1 and Fact 1, and assume that  $k^* \in o(k)$  and  $k^* \in \omega(k^{4/5})$  (if we show that the time is  $\omega(1)$  for functions  $k^* \in \omega(k^{4/5})$ , the same remains true also for all smaller functions  $k^*$ ).

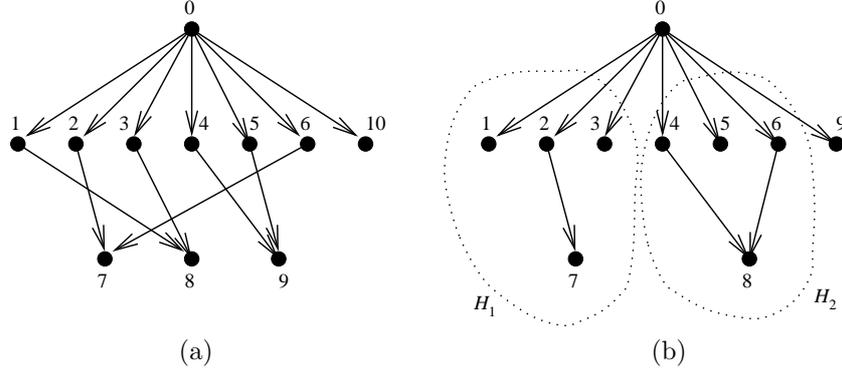

Figure 1: (a) Example of the network in the class used in the proof of Theorem 1, for  $n = 11$  and  $k = 3$ ; (b) Example of the network in the class used in the proof of Theorem 2, for  $n = 10$ ,  $n' = 3$ ,  $k = 2$ ,  $S_1 = \{2\} \subseteq \{1, 2, 3\}$  and  $S_2 = \{4, 6\} \subseteq \{4, 5, 6\}$

The proof is by contradiction. Fix an oracle giving advice of size at most  $k^*$  to networks from the family  $\mathcal{C}$ , and an algorithm using this oracle and completing the broadcast in all these networks in time at most  $c^*$ . Let  $\mathcal{C}(\ell)$  be the subfamily of  $\mathcal{C}$  for which the oracle gives  $\ell$  bits of advice to the source, for  $0 \leq \ell \leq k^*$ , and gives the remaining bits to some other nodes of the network. For a sequence  $\hat{y}$  of  $\ell$  bits, let  $\mathcal{C}(\ell)_{\hat{y}}$  be the subfamily of  $\mathcal{C}(\ell)$  containing those networks for which the oracle gives the advice  $\hat{y}$  to the source.

Fix  $0 \leq \ell \leq k^*$ . There are  $2^\ell$  possible advice sequences in the source, and at least  $k - k^* + \ell$  groups none of whose nodes has any advice. We call these groups *blind groups*. Fix a sequence  $\hat{y}$  of  $\ell$  bits of advice in the source and consider the transmission sequence of length at most  $c^*$  for each node in  $\{1, \dots, 2k\}$  assuming that it has no bit of advice and that the source has the advice  $\hat{y}$ . Formally, the transmission sequences can be longer, but it is sufficient to consider only prefixes of length at most  $c^*$  for the purpose of proving the lower bound. Under this assumption and due to the fact that the source is the only in-neighbor of nodes in layer  $L_1$ , each such node without any advice has a fixed 0-1 transmission sequence of length  $c^*$ , since no feedback is possible, due to the absence of directed cycles in the graph. (In a transmission sequence, 0 in position  $i$  means that the node does not transmit in round  $i$ , and 1 means that it transmits.) This yields a partition of nodes  $\{1, \dots, 2k\}$  into at most  $a = 2^{c^*} = \frac{k-k^*}{2k^* \log(ke/k^*)}$  colors, where all nodes of the same color follow the same transmission pattern during the first  $c^*$  rounds. Note that  $a^4 \in o(k^*)$ , by the assumption  $k^* \in \omega(k^{4/5})$ . In every network in  $\mathcal{C}(\ell)_{\hat{y}}$ , nodes of every blind group must have different colors, because otherwise both nodes would follow the same pattern of transmissions and their out-neighbor would not receive the source message by round  $c^*$ . Therefore, the number of networks in class  $\mathcal{C}(\ell)_{\hat{y}}$  is at most

$$\binom{k}{k^* - \ell} \binom{2k}{2(k^* - \ell)} \frac{(2k^* - 2\ell)!}{2^{k^* - \ell}} \cdot 2^{-(k - k^* + \ell)} \cdot \beta(2k - 2k^* + 2\ell, a) ,$$

where  $\beta(2x, a)$  is the upper bound from Lemma 3. In the above formula the first factor corresponds to the number of choices of non-blind groups (and possibly some blind ones, since the number of non-blind groups is *at most*  $k^* - \ell$ ) among all groups. The second factor corresponds to the number of choices of the  $2(k^* - \ell)$  elements to be allocated to the above groups. The third factor corresponds to the number of ways of allocating these elements to these groups. The last two factors form an upper bound on the number of different configurations of the remaining nodes such that the remaining (blind) groups are not monochromatic (i.e., the number of permutations without remaining monochromatic blind groups, divided by the number of possible flips of elements inside those groups—there are  $2^{k - k^* + \ell}$  such flips).

Using Lemma 3 and the properties  $k^* \in \omega(k^{4/5})$  and  $a^4 \in o(k^*)$ , we get the following fact.

**Fact 1.** For sufficiently large  $k$ ,

$$|\mathcal{C}(\ell)_{\hat{y}}| \leq \binom{k}{k^* - \ell} \cdot \delta \cdot e^{-k^* \log(ke/k^*) - 1} .$$

Proof of Fact 1: Using Lemma 3 and the properties  $k^* \in \omega(k^{4/5})$  and  $a^4 \in o(k^*)$ , we get

$$\begin{aligned} \beta(2k - 2k^* + 2\ell, a) &= \sqrt{2} \cdot (2k - 2k^* + 2\ell)! \cdot e^{2a^2 \ln(e(2k-2k^*+2\ell)/a) - (k-k^*+\ell)/a} \\ &\leq \sqrt{2} \cdot (2k - 2k^* + 2\ell)! \cdot e^{2a^2 \ln(2ek) - \frac{k-k^*}{(k-k^*)/(2k^* \log(ke/k^*))}} \\ &\leq (2k - 2k^* + 2\ell)! \cdot e^{-k^* \log(ke/k^*) - 1} , \end{aligned}$$

for sufficiently large  $k$ . Therefore, we obtain

$$\begin{aligned} |C(\ell)_{\hat{y}}| &\leq \binom{k}{k^* - \ell} \cdot \binom{2k}{2(k^* - \ell)} \cdot \frac{(2k^* - 2\ell)!}{2^{k^* - \ell}} \cdot 2^{-(k-k^*+\ell)} \cdot (2k - 2k^* + 2\ell)! \cdot e^{-k^* \log(ke/k^*) - 1} \\ &= \binom{k}{k^* - \ell} \cdot \frac{(2k)!}{(2k^* - 2\ell)!(2k - 2k^* + 2\ell)!} \cdot \frac{(2k^* - 2\ell)!}{2^k} \cdot (2k - 2k^* + 2\ell)! \cdot e^{-k^* \log(ke/k^*) - 1} \\ &= \binom{k}{k^* - \ell} \cdot \frac{(2k)!}{2^k} \cdot e^{-k^* \log(ke/k^*) - 1} \\ &= \binom{k}{k^* - \ell} \cdot \delta \cdot e^{-k^* \log(ke/k^*) - 1} . \end{aligned}$$

◇

Finally, using Fact 1 and Lemma 1, we can bound

$$\begin{aligned} |C| &= \sum_{\ell=0}^{k^*} \sum_{\hat{y}} |C(\ell)_{\hat{y}}| \leq \sum_{\ell=0}^{k^*} \sum_{\hat{y}} \left( \delta \cdot \binom{k}{k^* - \ell} \cdot e^{-k^* \log(ke/k^*) - 1} \right) \\ &\leq \sum_{\ell=0}^{k^*} \left( 2^\ell \cdot \delta \cdot e^{-2\ell} \cdot e^{k^* \ln(ke/k^*)} \cdot e^{-k^* \log(ke/k^*) - 1} \right) \\ &\leq (\delta/e) \cdot \sum_{\ell=0}^{k^*} e^{-\ell} < \delta , \end{aligned}$$

for sufficiently large  $k$ . This is a contradiction which completes the proof of Theorem 1. □

Our next result shows that if the advice is of sublogarithmic size, then the time required for broadcasting not only is not constant but sometimes quite large.

**Theorem 2.** *Fix any constant  $\delta < 1$ . There exists a constant  $c > 0$  such that, for sufficiently large  $n$ , there exists a family of  $n$ -node networks with constant optimal broadcasting time, for which every algorithm using at most  $c \log n$  bits of advice requires time at least  $n^\delta$  on some of them.*

PROOF. Fix any  $0 < \delta < 1$ . For a positive integer  $n$ , we set  $n' = \lceil n^\delta \rceil$  and  $k = \lfloor \frac{n-1}{n'+1} \rfloor$ . For  $n$  large enough, there exists  $0 < \epsilon < 1$  such that  $k \geq n^\epsilon$ . For any  $k$ -tuple  $\mathcal{S} = (S_1, S_2, \dots, S_k)$ , where each  $S_i$ ,  $1 \leq i \leq k$ , is an arbitrary non-empty subset of  $\{1, \dots, n'\}$ , we define the directed graph  $G_{\mathcal{S}}$  as follows. The source is node 0. It has directed edges to  $k \cdot n'$  nodes labelled from 1 to  $k \cdot n'$ . For any  $1 \leq i \leq k$ , if  $j \in S_i$  then node  $(i-1)n' + j$  has a directed edge to node  $k \cdot n' + i$ . Finally, in order to have exactly  $n$  nodes, the source has directed edges to the nodes from  $k(n'+1) + 1$  to  $n-1$ , if any. Hence the graph has  $k$  disjoint  $(n'+1)$ -node subgraphs  $H_1, \dots, H_k$ , attached to the source. More precisely, the subgraph  $H_i$  is induced by the nodes  $(i-1)n' + 1, \dots, i \cdot n', k \cdot n' + i$ . The directed edges inside a subgraph  $H_i$  are determined by the set  $S_i$ . The set of graphs  $G_{\mathcal{S}}$ , for all possible  $\mathcal{S}$ , is denoted  $\mathcal{G}$ . See Fig. 1(b).

We prove that there is no algorithm using advice of size  $q \leq \frac{1}{2} \log k$  that achieves broadcast in the family  $\mathcal{G}$  in time smaller than  $n'$ . Fix an algorithm using advice of size  $q \leq \frac{1}{2} \log k$ . Let  $s_1, \dots, s_Q$ , for  $Q = 2^{q+1} - 1$  be an enumeration of all binary sequences of length at most  $q$  (including the empty sequence). First note that  $Q \cdot (q+1) \leq k$ , for sufficiently large  $n$ . Consider the following property:

For any  $1 \leq i \leq Q \cdot (q + 1)$ , there exists a non-empty subset  $S_i$  of  $\{1, \dots, n'\}$  such that for any  $k$ -tuple  $\mathcal{S}$  containing  $S_i$  as the  $i$ -th element we have that, in the graph  $G_{\mathcal{S}}$ , either

- (1) the source has advice different from  $s_j$ , where  $j = \lfloor \frac{i-1}{q+1} \rfloor$ , or
- (2) at least one node of the subgraph  $H_i$  receives at least one bit of advice.

This implies that for a  $k$ -tuple  $\mathcal{S}$  such that the  $Q \cdot (q + 1)$  first elements are the above mentioned sets  $S_i$ , there exist at least  $q + 1$  different subgraphs  $H_i$  receiving at least one bit. Indeed, if the advice given to the source is  $s_j$ , each of the graphs  $H_i$ , for  $i = (j - 1)(q + 1) + 1, \dots, j(q + 1)$ , gets at least one bit. This contradicts the fact that the total size of advice is at most  $q$ .

Therefore, the property does not hold. This means that there exists an integer  $i \leq k$  such that for any non-empty subset  $S_i$  of  $\{1, \dots, n'\}$ , there exists a  $k$ -tuple  $\mathcal{S}$  containing  $S_i$  as the  $i$ -th element such that, in the graph  $G_{\mathcal{S}}$ , the source has advice  $s_j$ , where  $j = \lfloor \frac{i-1}{q+1} \rfloor$ , and the subgraph  $H_i$  receives no bit of advice. In other words, there exists an index  $i$  and a subfamily  $\mathcal{G}'$  of  $\mathcal{G}$  such that for each graph in  $\mathcal{G}'$  the source always receives the same string while the subgraph  $H_i$  never receives any advice from the oracle; moreover, for any non-empty subset  $S_i$  of  $\{1, \dots, n'\}$ , there exists a graph in  $\mathcal{G}'$  where the graph  $H_i$  is constructed from  $S_i$ . Therefore, for this subgraph  $H_i$ , the situation is identical as if it were alone (the graph is directed) and as if there were no oracle. Since there are no directed cycles in the graph, no node can receive any feedback, and hence any broadcasting algorithm in such a graph is oblivious. Therefore, using the argument from the proof of Theorem 2.2. in [25], for some graph  $H_i$  the time of informing node  $k \cdot n' + i$  is at least  $n'$ . (The quoted theorem says that the worst-case time of waking up a complete radio network, some of whose nodes are woken up by the adversary, is at least equal to the number of all nodes.) This implies that there exists a graph in  $\mathcal{G}'$  in which the algorithm does not achieve broadcast in time less than  $n'$ . Since  $n' \geq n^\delta$  and  $\frac{1}{2} \log k \geq c \log n$ , for  $c = \epsilon/2$ , this proves the theorem.  $\square$

### 3.2. Geometric Radio Networks

We finally show that the large advice requirements established in the previous section do not hold in the more restricted class of geometric radio networks. Indeed, for these networks we have the following result which should be contrasted with Theorems 1 and 2.

**Theorem 3.** *For any positive constant  $c$  let  $\mathcal{G}$  be the class of geometric radio networks whose optimal broadcasting time is at most  $c$ . There exists an oracle which gives advice of constant size to the nodes of networks of class  $\mathcal{G}$  and an algorithm using this advice, which performs broadcast in constant time  $c'$ , for any network in class  $\mathcal{G}$ .*

To prove Theorem 3 we will use the following construction. Fix the ranges  $r_1 < \dots < r_\rho$ . (Recall that both the number  $\rho$  of ranges and the ranges themselves are constants.) Partition the plane into a mesh of squares of side  $z = r_1/\sqrt{2}$ , called *tiles*, with the bottom-left corner of one of them in  $(0, 0)$ . Include the left and bottom sides and exclude the top and right sides from every square. Knowing its position, every node knows to which tile it belongs. The tile to which the source belongs is called *central*. Observe that any two nodes belonging to the same tile are within each other's range. For any positive integer  $x$ , the  $x$ -*block* is a square consisting of  $B(x) = (2x + 1)^2$  tiles with the central tile in the center of this square.

A configuration of points in the plane yielding a geometric radio network with optimal broadcasting time at most  $c$  must have the property that the most distant points are at distance at most  $2cr_\rho$  and hence all points are contained in a  $d$ -block, for some positive constant  $d$ . Take the smallest such integer  $d$ . Order all the  $B(d)$  tiles of the  $d$ -block in a fixed way, giving them indices  $1, \dots, B(d)$  and then order the  $p(d) = B(d)(B(d) - 1)$  ordered pairs of these indices in a fixed way, giving them indices  $1, \dots, p(d)$ . Let  $\lambda(a, b)$  denote the index of the pair  $(a, b)$ , where  $a, b$  are (indices of) distinct tiles.

*Advice..* We now describe the oracle, called Geometric Oracle in the sequel. Consider an ordered pair  $(a, b)$  of distinct tiles of the  $d$ -block. If there is a pair  $(u, v)$  of nodes in tiles  $a$  and  $b$ , respectively, such that  $v$  is in the range of  $u$ , choose one such a pair. The oracle gives advice  $(\lambda(a, b), out)$  to  $u$  and advice  $(\lambda(a, b), in)$  to  $v$ . Clearly, the same node can get many pieces of advice, however, for constant  $d$ , the total number of bits of advice is constant. Moreover, any node that received the above advice, gets additionally the integer  $d$ .

We now describe the algorithm using the advice obtained from Geometric Oracle. It uses global round numbers which are transmitted from node to node appended to the source message.

*Algorithm GRN-Broadcasting-with-Advice.* The algorithm lasts  $1 + 2p(d)B(d)$  rounds. After round 1 it is divided into  $B(d)$  identical stages, each lasting  $p(d)$  2-round periods. The pseudo-code follows:

in round 1 the source transmits;  
 starting in round 2, **repeat**  $B(d)$  times procedure **Stage**

where **Stage** is the following subroutine:

**for**  $i := 1$  to  $p(d)$  **do**  
   **if**  $u$  has advice  $(i, out)$  and got the source message  
     **then** it transmits in the *first* round of period  $i$  of this stage  
   **if**  $u$  has advice  $(i, in)$  and got the source message  
     **then** it transmits in the *second* round of period  $i$  of this stage

Theorem 3 follows from the following lemma.

**Lemma 4.** *Algorithm GRN-Broadcasting-with-Advice, using the Geometric Oracle, is correct and has constant running time.*

PROOF. Consider any node  $v$  of the network with source  $s$ . Since there exists a directed path from  $s$  to  $v$ , we can find a sequence of tiles  $(T_0, T_1, \dots, T_y)$  of the  $d$ -block, for  $y < B(d)$ , such that  $s \in T_0$ ,  $v \in T_y$ , and for any  $j < y$  there exist  $u_j \in T_j$  and  $u_{j+1} \in T_{j+1}$  such that  $u_{j+1}$  is in the range of  $u_j$ . After round 1, all nodes of tile  $T_0$  are informed. The following property is easily shown by induction on  $j$ : after  $j$ th **Stage**, all nodes of tile  $T_j$  get the source message. Hence, by the end of the algorithm, node  $v$  gets the source message. Note that the running time of the algorithm depends only on  $d$  and thus is constant.  $\square$

#### 4. The General Algorithm

In this section we design and analyze a broadcasting algorithm working for arbitrary radio networks, whose running time is inverse-proportional to the size of advice given to nodes. We prove the following theorem.

**Theorem 4.** *For any  $q \in O(n)$  there exists an oracle which gives advice of size  $q$  to the nodes of a network and an algorithm using this advice, which performs broadcast in time  $O(\frac{nD}{q} \log^3 n)$  in any  $n$ -node network with source eccentricity  $D$ .*

We prove Theorem 4 by constructing an appropriate oracle and algorithm. First assume that  $q \in O(D \log n + \log^2 n)$ . In this case we can use the broadcasting algorithm from [12] running in time  $O(n \log^2 D)$  without using any advice, since  $O(n \log^2 D) \subseteq O(\frac{nD}{q} \log^3 n)$ , for this range of  $q$ . Therefore, in the sequel, we can assume  $q \geq 6(D \log n + \log^2 n)$ . We first define a specific clustering of a given graph to be used by the oracle. Next we specify the advice given by the oracle to the nodes. Finally, we formulate an algorithm using this advice, and argue about its complexity.

The high-level idea of the advice provided to the nodes and of the algorithm using this advice is as follows. We would like to use selective families (c.f., e.g., [11]) in a way that was already explored in the context of ad-hoc radio networks (i.e., without advice). The main problem with this approach is, however, that in order to deliver the source message to a node with large in-degree a “long” selective family has to be used, which in turn increases the time beyond the target complexity. Therefore we may use this approach only for the purpose of delivery to the nodes with relatively small in-degree. For the remaining nodes, a clustering of BFS-layers is done in such a way that any node of large in-degree can be informed when some single cluster transmits according to some short selective family. Since there is only a logarithmic

number of clusters in each BFS layer and the selective family is short, an appropriate scheduling of cluster transmissions, each according to the corresponding selective family, guarantees successful broadcast within the sought time complexity. The control information indicating which selective family to start and when, and which cluster is going to transmit and when, is provided to the nodes by the advice.

*Clustering.* Given the directed graph  $G = (V, E)$  with source  $s$ , let  $L_1, \dots, L_D$  be BFS layers in  $G$ , i.e., sets of nodes at distance exactly  $i$  from the source, for  $1 \leq i \leq D$ . Let  $T$  be the smallest power of 2 greater or equal to  $1152 \frac{n}{q} \log^2 n$ . The clustering of graph  $G$  consists of sets of nodes  $L_i(j)$ , for  $1 \leq i \leq D-1$  and  $j = \log T, \log T + 1, \dots, \lfloor \log |L_i| \rfloor$ , such that for every  $i$  and  $\log T \leq j \leq \lfloor \log |L_i| \rfloor$ , we have  $L_i(j) \subseteq L_i$  and the following properties hold:

- (i) every node in  $L_{i+1}$  having at least  $2^j$  and less than  $2^{j+1}$  neighbors in  $L_i$ , has at least 1 and at most  $144 \log n$  neighbors in  $L_i(j)$ ;
- (ii)  $|L_i(j)| < 144 |L_i| \log n / 2^j$ .

The following lemma justifies the existence of such a clustering.

**Lemma 5.** *For every  $1 \leq i \leq D-1$  and  $j = \log T, \log T + 1, \dots, \lfloor \log |L_i| \rfloor$ , there exists a set  $L_i(j) \subseteq L_i$  with the above properties (i) and (ii).*

PROOF. The lemma is proved by the probabilistic method. Fix  $i \in \{1, \dots, D-1\}$  and  $j \in \{\log T, \log T + 1, \dots, \lfloor \log |L_i| \rfloor\}$ . Form the set  $L_i(j)$  by putting in it each element from  $L_i$  with probability  $96 \log n / 2^j$ , independently. Note that  $96 \log n / 2^j \leq 96 \log n / T$ , which is smaller than  $1/2$  for sufficiently large  $n$ , since  $q \in O(n)$ . It follows that each node having  $x$  neighbors in set  $L_i$ , where  $2^j \leq x < 2^{j+1}$  for some integer  $\log T \leq j \leq \log |L_i|$ , has at least  $48 \log n$  and at most  $96 \log n$  of expected neighbors in set  $L_i(j)$ , and by Chernoff bound it has at least  $24 \log n$  and at most  $144 \log n$  neighbors in  $L_i(j)$  with probability at least  $1 - 2 \exp(-48 \log n / 12) \geq 1 - 2/n^2$ . On the other hand, with probability at least  $1 - \exp(-96 |L_i| \log n / 2^j / 12) \geq 1 - 1/n^8$  we have  $|L_i(j)| < 144 |L_i| \log n / 2^j$ , again by Chernoff bound and using the fact that the expected size of set  $L_i(j)$  is  $96 |L_i| \log n / 2^j$ . Summarizing, the probability that properties (i) and (ii) hold for the fixed  $i$  and  $j$  is at least  $1 - |L_i| \cdot 2/n^2 - 1/n^8 \geq 1 - 2/n > 0$  and therefore the set  $L_i(j)$  satisfying the required properties exists, which proves the lemma.  $\square$

*Advice.* We now describe the advice given by the oracle. The advice given to the source consists of integers  $N, n, q$  and of the sizes of layers  $L_1, \dots, L_D$ . (Recall that  $N$  is an upper bound on all labels, polynomial in the number  $n$  of nodes.) This can be encoded using  $3D \log n \leq q/2$  bits of advice. Moreover, to every node in set  $L_i(j)$ , for  $1 \leq i \leq D-1$  and  $\log T \leq j \leq \log |L_i|$ , the oracle gives the integer  $j$ . (Note that, since sets  $L_i(j)$  are not necessarily disjoint, a node may get several integers as advice.) This costs a total of at most

$$2 \cdot \sum_{i=1}^{D-1} \sum_{j=\log T}^{\lfloor \log |L_i| \rfloor} (144 |L_i| \log n / 2^j \cdot \log j) \leq 4 \cdot 144 \cdot (n/T) \log^2 n \leq q/2$$

bits, by property (ii) of sets  $L_i(j)$ . Hence the total size of advice is at most  $q$ .

*Algorithm Radio-Broadcasting-with-Advice.* We now describe the algorithm using the above advice. It uses global round numbers which are transmitted from node to node appended to the source message. First we define the additional information attached to the source message. We will use the notion of a  $(N, x)$ -selective family. This is a family  $\mathcal{F}$  of subsets of  $\{1, \dots, N\}$ , such that, for any set  $X \subseteq \{1, \dots, N\}$  of size at most  $x$ , there exists a set  $F \in \mathcal{F}$ , for which  $|F \cap X| = 1$ . For any  $x$ , fix a  $(N, x)$ -selective family  $\mathcal{S}(N, x)$  of size  $s(N, x)$ . By [11] there exist  $(N, x)$ -selective families of size  $O(x \log(N/x)) \subseteq O(x \log n)$ , thus we can assume that  $s(N, x) \leq b \cdot x \log n$  for some constant  $b > 0$ . Fix an order  $(F_1, \dots, F_{s(N, x)})$  of the family

$\mathcal{S}(N, x)$ . Knowing  $T$ , sizes  $|L_i|$  of layers and the constant  $b$ , the source computes the sequence of rounds  $t_1 < \dots < t_{D-1}$  recursively as follows:

$$\begin{aligned} t_0 &= 0 \\ t_{i+1} &= t_i + s(N, T) + (\log |L_i| - \log T + 1) \cdot s(N, \lceil 144 \log n \rceil) \quad \text{for } 1 \leq i \leq D-1. \end{aligned}$$

Then the source broadcasts the source message together with the sequence  $t_1, \dots, t_{D-1}$  and  $|L_1|, \dots, |L_{D-1}|$  in round 0. A node that receives this message for the first time in round  $t$ , where  $t_{i-1} < t \leq t_i$  for some  $1 \leq i \leq D-1$ , waits till round  $t_i$  and starts transmitting according to the  $(N, T)$ -selective family  $\mathcal{S}(N, T)$ , starting in round  $t_i + 1$  until round  $t_i + s(N, T)$ . More precisely, a node with label  $u$  transmits in round  $t_i + y$ , if  $u$  is in  $F_y$ , where  $F_y$  is the  $y$ -th set of the family  $\mathcal{S}(N, T)$ . Additionally, if a node has the integer  $j$  in its advice string then it transmits according to the family  $\mathcal{S}(N, \lceil 144 \log n \rceil)$  in the time interval from  $t_i + s(N, T) + (j - \log T) \cdot s(N, \lceil 144 \log n \rceil) + 1$  to  $t_i + s(N, T) + (j + 1 - \log T) \cdot s(N, \lceil 144 \log n \rceil)$ , for any  $\log T \leq j \leq \log |L_{i+1}|$ . A node without the integer  $j$  in its advice string waits during this period. A node that receives the source message for the first time in round at most  $t_i$  does not transmit in rounds beyond  $t_{i+1}$ .

**Lemma 6.** *Assume  $q \in O(n)$  and  $q \geq 6(D \log n + \log^2 n)$ . Our algorithm Radio-Broadcasting-with-Advice performs broadcasting in any  $n$ -node network with source eccentricity  $D$  in time  $O(\frac{nD}{q} \log^3 n)$  using at most  $q$  bits of advice.*

PROOF. In order to prove the correctness of the algorithm it is enough to show that by round  $t_i$  all nodes in layers  $L_1, \dots, L_{i+1}$  are informed, for  $0 \leq i \leq D-1$ , and none of the nodes in the other layers (apart from the source) is. The proof is by induction on  $i$ . It is straightforward that each node in  $L_1$  gets the message in round  $t_0 = 0$  and no other node does. Assume that each node in layers  $L_1, \dots, L_{i+1}$ , for  $0 \leq i \leq D-2$ , gets the source message by round  $t_i$ , and no other node except the source is informed by round  $t_i$ . We consider the time interval  $(t_i, t_{i+1}]$ , and we call it the *epoch*  $i+1$ . Consider a node  $v \in L_{i+2}$ . We want to show that it becomes informed in epoch  $i+1$ . The inductive assumption holds for all its neighbors in layer  $L_{i+1}$ . Only those neighbors of  $v$  in graph  $G$  are active in epoch  $i+1$ . If  $v$  has at most  $T$  neighbors in layer  $L_{i+1}$  then during the transmissions performed according to the family  $\mathcal{S}(N, T)$  by all nodes in  $L_{i+1}$  at the beginning of epoch  $i+1$ , node  $v$  receives the source message. Otherwise,  $v$  has  $x$  neighbors in layer  $L_{i+1}$ , where  $2^j \leq x < 2^{j+1}$ , for some  $\log T \leq j \leq \log |L_{i+1}|$ . In view of property (i) of sets  $L_i(j)$ , it follows that  $v$  has at least one and at most  $144 \log n$  neighbors in set  $L_{i+1}(j)$ . Therefore it is informed between round  $t_i + s(N, T) + (j - \log T) \cdot s(N, \lceil 144 \log n \rceil) + 1$  and round  $t_i + s(N, T) + (j - \log T + 1) \cdot s(N, \lceil 144 \log n \rceil)$ , when only nodes in  $L_{i+1}(j)$  transmit according to the family  $\mathcal{S}(N, \lceil 144 \log n \rceil)$ . Note that the above period is contained in epoch  $i+1$ . This completes the proof that  $v$  gets the source message in epoch  $i+1$ .

Now we argue that no node in layer  $L_k$ , for any  $k > i+2$ , receives the source message in epoch  $i+1$ , since in this period only nodes in layers  $L_1, \dots, L_{i+1}$  transmit (a node  $v \in L_{i+2}$  starts its protocol in round  $t_{i+1} + 1$  at the earliest, since it receives the source message in the period  $(t_i, t_{i+1}]$  for the first time, by the argument above). Thus the inductive proof is finished, which means that all nodes receive the source message by round  $t_{D-1}$ , and hence the algorithm is correct.

Since in the description of the advice given by the oracle we have already shown that the size of advice is indeed at most  $q$ , it remains to analyze the running time of the algorithm. We have  $t_0 = 0$ , and  $t_{i+1} = t_i + s(N, T) + (\log |L_i| - \log T + 1) \cdot s(N, \lceil 144 \log n \rceil) \leq t_i + b \cdot (T + (\log |L_i| - \log T + 1) 145 \log n) \log n \leq t_i + bT \log n + 145b \log^3 n$ , for  $1 \leq i \leq D-2$ . It follows that  $t_{D-1} \leq bTD \log n + 145bD \log^3 n \in O(\frac{nD}{q} \log^3 n)$ , since  $q \in O(n)$ .  $\square$

Since, as we noticed before, for  $q \in O(D \log n + \log^2 n)$ , the time  $O(\frac{nD}{q} \log^3 n)$  of broadcasting can be achieved even without advice, Lemma 6 concludes the proof of Theorem 4.

**Corollary 1.** *For  $n$ -node networks with source eccentricity  $D$  polylogarithmic in  $n$ , there exists advice of size  $o(n)$  sufficient to achieve  $\text{polylog}(n)$  broadcasting time.*

The above corollary should be contrasted with the lower bound from [11], where it is shown that (without advice) some  $n$ -node networks with source eccentricity  $D$  require time  $\Omega(n \log D)$ .

## 5. Conclusion

We studied the impact of the size of information (advice) given to nodes of a radio network on the time of broadcasting. Our approach was quantitative, i.e., we were concerned with the total number of bits, as opposed to particular items of information, such as the knowledge of neighborhood, or of the size of the network, whose impact on broadcasting time was previously studied in the literature. While our algorithm is a first step towards grasping the trade-off between the size of advice and the time of broadcasting, establishing the exact trade-offs, for any number of bits of advice, remains an open problem. Its general formulation is: What is the minimum time to broadcast in radio networks, with advice of size  $q$ ? A more specific question is: What is the minimum size of advice permitting to achieve broadcasting time  $O(\text{Opt}(G))$  for any radio network  $G$ . We answered this question for networks with constant optimal time.

Establishing trade-offs between the size of advice and broadcasting time is also open for geometric radio networks. For these networks time  $O(D)$ , where  $D$  is the eccentricity of the source, is optimal under full knowledge of the network. It is easy to show that  $O(\min(n, D^2))$  bits of advice are sufficient to achieve this time. Indeed, advice of size  $n$  is clearly sufficient because it is enough to give bit 1 to every node that should transmit the source message (in the round after it got it first). Advice of size  $O(D^2)$  is also sufficient for the following reason. There are only  $O(D^2)$  non-empty tiles. From each tile only a constant number of tiles can be potentially reached. Hence in each tile there is only a constant number of nodes that need to transmit. These nodes get bit 1 as advice. The question is if the size  $\Omega(\min(n, D^2))$  of advice is also necessary.

Another interesting problem is to compare the size of arbitrary advice permitting given broadcasting time with the size of advice of given type, e.g., concerning the immediate neighborhood. It was proved in [26] that giving to all nodes information about their immediate neighborhood (a total of  $\Theta(|E| \log n)$  bits) permits broadcasting in time  $O(n^{2/3} \log n)$  in networks with source eccentricity 2. In [3] it was proved that time  $\Omega(\sqrt{n})$  is necessary for these networks with this information. This should be contrasted with the algorithm from the present paper which, e.g., permits broadcasting in these networks in the same time  $O(n^{2/3} \log n)$  using only  $O(n^{1/3} \text{polylog}(n))$  bits of advice, provided that the advice is of non-restricted type. On the other hand,  $O(\sqrt{n} \text{polylog}(n))$  bits of advice suffice to beat time  $\Theta(\sqrt{n})$  for these networks. These examples suggest that using advice of non-restricted type may be much more efficient than that of a particular type.
