Chapter 4: Functions

Author: Vincent Delecroix
License: CC BY-SA 3.0

The aim of this fourth chapter is to introduce you to write yourself your own function. This is useful if you want to reuse many times the same piece of code while not copy/pasting it.

The structure of a function is always the same:

```python
sage: def f(n):
    ....:     f = n.prime_factors()
    ....:     return f[-1] + 1
```

Exercise 4.1

Write a function computing the area of a triangle from the length of the three sides:

```python
sage: # edit here
```

Exercise 4.2

The duration of sunshine $D(\beta,d)$ on a given place on Earth is given by the formula

$$D(\beta,d) = 24 - \frac{24}{\pi} \arccos \left( \tan \beta \cdot \tan \left( \arcsin \left( \sin(\kappa) \cdot \sin \left( \frac{2\pi}{365}d \right) \right) \right) \right)$$

where $\kappa = \frac{23\,441}{180}$ is the inclination of the earth in radian, $d \in [0,365]$ is the number of days after the spring equinox and $\beta \in [-\pi/2,\pi/2]$ is the latitude of the place in question. Write the function $D(\text{beta, d})$:

```python
sage: # edit here
```

Construct the list of duration of sunshine in Marseille for the 31 days of the month of July 2017:

```python
sage: # edit here
```

Exercise 4.3

Let the sequence $u_{n+1} = \frac{1}{1+u_n}$ with $u_0 = 0$. Write a function $U(n)$ which returns the value of $u_n$. Compute $u_{20}$:

```python
sage: # edit here
```

Exercise 4.4

Write a function `product_of_digits(n)` which returns the product of the digits of $n$ written in base 10:

```python
sage: # edit here
```
Exercise 4.5

The number 6 is called a perfect number, because it is equal to the sum of its proper divisors: $6 = 1 + 2 + 3$. Write a function `is_perfect(n)` which returns True or False whether the number $n$ is perfect:

```python
sage: # edit here
```

Find all four perfect numbers below 10000:

```python
sage: # edit here
```

Find all four perfect numbers below $10^6$:

```python
sage: # edit here
```
